Question 6.—The answers to this have been many and curious. In some cases they have disowned all knowledge of the existence of any other company, and in nearly every case they seem to be imbued with the rivalry quarrels or misunderstandings of the various parent or manufacturing companies whose apparatus they are using.

Copies of the circulars, together with a letter explaining more fully the plan suggested by your committee, were sent to all the manufacturing companies. They were also requested to furnish the committee with a list of the particular railways operating under their systems. After much correspondence and many personal interviews your committee would announce that they have written authority from both the Thomson-Houston and Sprague Street Railway Companies to make the statement, on behalf of their particular companies, that they will agree hereafter to use a standard potential of 500 volts upon all electric street-railway equipments that do not require any special apparatus for their successful operation.

In recommending electric light companies to add to their regular central station business the business of furnishing power to street railroads, we wish it fully understood that we do not base any hopes of profits to be made upon the old-time idea that the same machinery can be used for furnishing light at night and power in the day-time. This specious argument has led many companies into large expenditures for motors, &c., and they have discovered later that it costs very nearly twice as much money to run the same machinery night and day as to run it at night alone, and that it pays better in the long run to have an entirely different class of apparatus to produce light and power. The true direction from which returns may be expected, in the massing in large stations of the generation of electricity for both light and power, is found in the fact that any electric light station, to be sure of continuous running, requires a reserve of from 15 to 25 per cent. of its average load in boilers, engines, and dynamos; the percentage being larger in small stations, and diminishing as the station increases in size. This same reserve in capacity is required for the power station; but on street-car work, in most of the stations hitherto installed, this percentage runs very much higher, being from 50 to 80 per cent. Now, if any one station supplying electricity for all purposes in a town we have say 25 per cent. reserve in boilers, and 25 per cent. reserve in steam engines, in excess of the average load, we shall only require to place 25 per cent. reserve each on electric light dynamos and power generators to have practically the same result as though we had two complete and separate stations for electric light and for electric power, each with its proper reserve of 25 per cent. extra in engines and boilers and dynamos.

As an instance of what may be done in increasing the output of a station without a corresponding increase in expenses, we quote the case of a small station, which, as nearly as can be determined from results, shows the following condition of affairs. The station increased its business in 1889, over 1888, 23 per cent., and in the same time the total expenses, including the extra line work and distribution expenses, 10 per cent., which 10 per cent. meant 10 per cent. increase in running expenses and 10 per cent. in fixed expenses. The Company contemplates a further increase of 27 per cent. on the same basis; this increase, however, being for power furnished alone, without any line work involved, the most careful calculation shows that this will only increase the present running expenses 10 per cent., without increasing the fixed charges at all. In 1888 the fixed charges and running expenses were 25 per cent. and 75 per cent. respectively of the total expenses. In 1889 this same proportion held good, each having been increased 10 per cent. as above stated, and the total expenses having increased the same amount. The further expected increase, being 10 per cent. of 75 per cent., will mean an increase in the total expenses in 1890 over 1888 of 17 1-2 per cent., while in the same time the total output of the station and consequent gross receipts will have increased 50 per cent. These figures are all taken from the case of a small station, with a total output of some 350 horse-power, and a fresh increase in this station (above this point) will result in an entirely different condition of affairs, so that a readjustment will take place in the proportion of fixed expenses and running expenses. We therefore present the report of another station, which is operating 1,200 horse-power, in which the total operating expenses are divided into 80 per cent. running and 20 per cent. fixed. On increasing the station to an output of 1,800 horse-power; the increase to be entirely in the furnishing of power, the increase on total operating expenses would be about 14 per cent., and the ratios of fixed and running expenses would be as 15 per cent. and 85 per cent.

The great saving for the central station company lies in the reducing in labour and fixed charges, and also that the reserve power for one will suffice for the other. Your committee feel that a great step has been taken in the right direction in securing the endorsement and co-operation of the largest and leading companies, and they would suggest to the Association that some measures be taken to secure from the stationary motor companies the adoption of some standard potentials for their use upon constant-potential circuits.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

The following paragraphs of our New York correspondent's letters were held over last week owing to the pressure on our space. Up to the time of our going to press our New York letter for this week had not come to hand.

The Cincinnati Telephone Company and the Single Trolley System.—Going counter to a number of decisions rendered in favour of the railroad interests, Judge Taft, of Cincinnati, has decided against the single trolley system there, and has ruled that the double trolley system must be used. The decree, however, is subject to a stay of six months, and even then is open for extension, and in the meantime the electric railway companies have taken immediate action for an appeal. Judge Taft held that the telephone people have used their present system for eight years along the streets occupied by the railroad companies. The usual method of conducting the telephone business had been to use the earth as a return circuit in the outgoing wires, and the company had a lawful franchise to operate such a system. The railroad company also had a right under the law to use electricity to propel its cars, but it did not have the right, in the absence of express Legislative authority, to use such a system as would disturb and injure the business of the telephone company unless it should be shown that there was something in their manner of constructing the railway which would not create such disturbances as have been complained of. He considered the evidence to show that the double trolley system was practicable electrically and mechanically, and would do away with the trouble; whereas, on the contrary, while the telephone people might cure the trouble by using a metal circuit on each of its lines, that would involve such an enormous outlay of money as to be prohibitive, while a more economical arrangement would only partly relieve the difficulty. The single trolley was, therefore, a legal injury to the plaintiff. It has been remarked, I may add, that the metallic system was long ago approved of and recommended by the leading telephonists themselves, and that it has already been found necessary in such cities as New York, for instance, where there are really no electric railroads.

Attempts to Restrict Voltages.—A serious effort has just been made in the State of Virginia to restrict voltages. A hearing on the subject was had a few days ago at Richmond, in which no less an important and distinguished personage than Mr. Edison took a part, his presence there bringing together a crowded and representative audience. The proposal was opposed by nearly all the local companies in the State; and the Committee of the Legislature having the matter in hand, after hearing all the pros and cons, decided unanimously to report against the proposed measure. In New York State we now have promise of a similar attempt, there being a Special Committee of Investigation from the Legislature, which has begun to hold meetings and call witnesses, and whose object seems to be the establishment of the contention that high voltage currents should not be allowed. There are about 75 or 100 local companies in this State, and it is believed that nearly every one of them will oppose tooth and nail any limitation of voltage.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

March 11, 1890.

At the last *séance* of the Société des Électriciens, M. Reignier gave some interesting particulars with regard to the machine he is constructing in conjunction with M. Bary, and which I have alluded to in a previous letter. MM. Reignier and Bary have made a great point of reducing the resistance of the magnetic circuit. By diminishing this they have been able to employ a very small magneto-motive force, and consequently to greatly diminish the weight of copper; and the total weight of the machine for a given output is, therefore, at the same time considerably reduced. The method adopted by M. Reignier for reducing the resistance of the air-gap consists in winding the armature with a conductor composed largely of iron. The machine described by M. Reignier is of the ring type. The armature conductors are compound, and consist of a strip of copper, sandwiched between two strips of iron, and kept together by the insulating covering. But as in a ring the external surface is larger than the internal surface, the strips of iron are only on the outside. The machine, which has actually been constructed, has an output of 10·5 kilowatts (70 volts and 150 amperes) at a peripheral speed of 10 metres per second (33 feet per second), and at an angular velocity of 1,800 revolutions per minute. The machine weighs 263 kilogrammes (580lbs.). Its output for weight is thus 40 watts per kilogramme (18·2 watts per lb.). This figure is undoubtedly far superior to any hitherto obtained; and here are some comparative figures on the subject:—

Watts per kilogramme.	Edison.	Desroziers.	Rechniewski.	Reignier-Bary.
Machine	9	21	215	40
Armature copper	500	—	800	1,800
Total copper.....	92	250	270	445

I should remark that the figures of the Rechniewski machine correspond to a peripheral speed of 16 metres per second (52·3ft. per second). The efficiency tests of the Reignier-Bary machine were made at the Laboratoire Central d'Électricité, and the electrical efficiency was found to be 94 per cent., and the commercial efficiency 90 per cent. We are thus able to see that, without diminishing the efficiency, Messrs. Reignier and Bary have been able to increase in a very large degree the *puissance spécifique*. The advantages of this are so self-evident that it is not worth while to mention them further.

The Compagnie Continentale Edison is about to increase the capacity of its station in the Faubourg Montmartre by the addition of a large battery of accumulators, each to weigh about 800 kilogrammes, and able to discharge at the rate of 1,000 amperes. These accumulators, although of a special type, will be constructed on the lines of those made by the Société pour le Travail Electrique des Métaux, which possesses a large factory at St. Ouen. The Compagnie Continentale Edison has also purchased a site in the Avenue Vendaine, in the Quartier Rouchouart, where they intend erecting a 3,000 horse-power station, which will be connected to the one mentioned above.

Owing to the termination of the lease, the Standardising Laboratory of the Société Internationale des Électriciens in the Rue Saint-Charles will shortly have to be moved. The Conseil Municipal has offered a site in the Rue Thomond to the Société at a nominal rent, on the condition that the Société submits its plans to the municipality, and hands over to the town of Paris at the end of 60 years any building that may be erected. The Société is, moreover, to carry out gratuitously all tests and standardising required by the municipality, and to reserve two scholarships for pupils nominated by the town.

On Monday, February 24th, a judgment was given in the action brought against the State by the Société Générale des Téléphones. M. Emile Laurent considered that the concession granted to the Société by M. Granet in July, 1886, was *ultra vires*, and had no legal value, not having been approved by the Chamber. M. Laurent at the same time appointed a committee of experts to estimate the value on September 1, 1889, of the telephone material belonging to the Société, and to fix the loss sustained by the Société by reason of the non-working of their system from September 1, 1889, the date of its being taken over by the State, to the 8th of the same month, the date of the termination of the concession. The committee of experts will consist of three members, one nominated by the State, one by the Société Générale des Téléphones, and the third by the Conseil de Prefecture de la Seine.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *March* 10, 1890.

The telephone service between the Bourses of Vienna and Budapest has been opened since January 1st. Three metallic circuit lines were run, two for the Bourse and one for the Exchange subscribers. The experiments, however, proved that when the three lines were used the induction and overbearing were so great that the use of the third line had to be abandoned, and only two used, though even then there was a great deal of overhearing. The lines were run, against the advice of the Austrian chief electrician, on a plan proposed by the Hungarian engineers; they are so twisted and crossed that contacts are constantly occurring, and a fourth circuit cannot be added without taking down the existing lines. If a fourth circuit could be added, and all four run on the plan proposed by Mr. Preece, there is little doubt that four could be worked where at present it is impossible to work three circuits. The line is run with 3 mm. silicium bronze wire.

The success of the Vienna-Prag line has created a demand for further trunk lines, and the Government propose this year to connect some of the larger Bohemian towns with Prag, to connect Reichenberg with Gablonz, and to run a separate line to Brünn, giving up the present line worked on the Van Rysselberghe system. Brünn is then to be connected with Prag, thus giving an alternative route from Prag to Vienna. The Vienna-Prag line runs through a district called the "Forrest quarter," about thirty miles from Vienna. Here the ice and snow freezing on to the wire, frequently 10-30cm. thick, caused frequent breakages to the silicium-bronze wire, interrupting the service. In order to meet the difficulty this part of the line has now been run with 5mm. iron wire, a distance of about 30 kilometres; the result has been so far very good, and the experiment has in nowise affected the good working of the line, speaking being as clear as before.

The Town Council of Vienna has published an elaborate account of the cost of their electric light installation in the Town Hall. There are in use 1,141 glow lamps and 17 arc lamps; these have burned 134,943 hours for the glow lamps and 18 for the arc lamps, an arc-lamp hour being reckoned 270 glow-lamp hours. These have cost 7,757·37fl., or 5·74 kreuzers (about 1½d.) per hour. It must not be forgotten, however, that the Town Hall is heated by steam, and that the same boilers are used to drive the dynamo engines which supply the heat to the whole of that vast building.

In Budapest the Town Council have given permission to the tramway company and Messrs. Ganz and Company to run a short experimental electric tramway through the town on the Zipernowsky one-rail system. Telephonic communication will shortly be established between Budapest and Szegedin. Messrs. Siemens and Halske are erecting a lead cable factory in Vienna.

CORRESPONDENCE.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—"Figures may be made to prove anything." Thus you echo the remarks of Mr. H. J. S. Heather; and, borrowing another phrase from the same correspondent, "I think we are justified in relying on figures if they are put together with some regard to common sense." Mr. Heather mentions among the traction expenses the wages of the driver, which is never included in the "horsing" estimates of tramway companies. It is very doubtful whether car drivers can be obtained for the figure given, viz., ·6d. per car mile, the average distance travelled by London cars being 70 miles per day, which would allow the driver only 3s. 6d., whereas as a rule he gets about 6s. per day.

Working on the basis of 70 miles per car per day, I will now endeavour to show how the items in my letter of August 23, 1889, are obtained.

1. Renewal of accumulators one penny per car mile. This represents 25,550d. per annum. Including reserve, there are about 3,000 plates used in the batteries of 150 ampere hours' capacity each. We should thus get 8½d. per plate for renewal The material for new plates costs about 3¾d., but the old material has a value of at least 50 per cent. of the new; consequently, we have still a balance of over 6½d. per plate for labour and profit. A most desirable business for anyone who understands it, whose works are not hampered with a huge capital, plus debentures,

Digitized by Google

and whose administration and office expenses can be kept considerably below £10,000 per annum.

2. Cost of electric energy, inclusive wages and depreciation, 1·64d. Allowing a large margin, I take 2 indicated horse-power hours per car mile, or about 10 per cent. more than Mr. Heather. A moderately economical steam plant of not less than 200 horse-power capacity should not cost more than £10 per horse-power per annum of 3,600 hours, as is the case in many factories and mills. This amount includes all possible charges, and refers to London prices of coal and labour. Our car requires a maximum of 140 horse-power hours per day; therefore, on the basis of £10 for 3,600 hours we obtain 1·33, to which we can add ·31d. per car mile for dynamos and switches, depreciation and attendance.

3. Motors and gearing at ·75d. gives close upon £80 per annum, equal to 30 per cent. on the gross price of the whole electrical equipment on the car, excepting accumulators.

I have no authentic information as to the cost of traction at Barking-road; but I know that the success or failure of this system will mainly depend upon the prime cost and maintenance of the accumulator. I am now experimenting with a storage battery which is made without "paste, paint, cement, or powder," which gives a higher discharge rate with less weight than any pasted type, and which, whilst being tolerably cheap to produce, promises a depreciation of less than ¾d. per car mile; and with this I hope to bring the cost of accumulator traction down to the desired "threepence."—Yours, &c.,

London: March 10, 1890. A. Reckenzaun.

THE WYNNE SYSTEM OF ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Prof. Ayrton's letter on my system of applying electricity to tramways contains the claim for priority which may confidently be expected from him whenever any electrical invention is made public.

The sneering allusion to my supposed American nationality, and to the extreme youth of my invention, as well as a slang expression which I do not understand, may be passed over with the silence they deserve. I shall, therefore, confine myself to dealing with Prof. Ayrton's specific claim to priority.

Prof. Ayrton bases these claims on his and Prof. Perry's patents, Nos. 783, 1881, and 2,395, 1883.

As I stated in my former letter, patent 783, 1881, refers to mechanical means of connecting sectional insulated rails of considerable length with a main insulated conductor, and for the single expressed purpose of reducing leakage of the current supplied to electrical trains.

That the sections of this insulated rail are of considerable length is apparent from the following quotation (patent No. 783, 1881, page 9, line 23, *et seq.*):—"In all our arrangements previously described the distance between each contact box and the next varies from about 20 to 50 feet, so that there are several contact boxes in each section of our insulated rail, and several sections of an insulated rail in one section of the line blocked; but the following illustrates one of our methods for making each section of our insulated rail or conductor which is rubbed by a passing train, a mile or more in length—in fact, as long as the particular system employed to insulate the rubbed conductor will allow." It is clear that the use of sections made so short as to provide for the protection of the public by keeping those sections which are charged under the car, has not occurred to Profs. Ayrton and Perry; in fact, from beginning to end of these patents there is not one word to show that the Professors had any other ideas than that of modification of Prof. Fleeming Jenkins' system of electrical trains; not one word as to the special difficulties of applying electricity to urban tramways, or to means for overcoming these difficulties.

I must also traverse the statement which Prof. Ayrton makes in his letter, in the following words:—"Then it is explained that the insulation of a conductor on the ground, as, for example, the ordinary rail, is sufficient in certain cases to enable it to be used as the sectional conductor."

Will he kindly point out where this explanation occurs? The sentence immediately preceding the above is a quotation from the *final* specification; the two lines he quotes in support of the above are from the *provisional* specification, and occur in the following sentence, which is markedly omitted in the final (783, 1881, page 2, line 28, *et seq.*):—"We may modify our apparatus by dispensing with a third elastic rubbing rail as before described, *insulating instead by the best known means* one of the carrying rails, dividing and insulating the said rail at the usual fishplate or other joint into sections of suitable length, insulated from one another as perfectly as may be. Contact between such sectionally-insulated rail and the main well-insulated conductor may be made by the wheel tire or special roller pressing upon long rods parallel to the rail with contact pieces at their ends." The italics are mine; there is not even in this any suggestion that they should be insulated at *each* fishplate joint. The contact boxes are specified 20 to 50 feet apart, and the insulated sectional rail lengths are some multiple of these distances.

A large portion of this patent is devoted to very ingenious methods of automatically blocking the line, so as to prevent the possibility of collisions between the trains; and with this portion of the patent I have at present nothing to do, as it in no way applies to tramways. The only reference to an electrical method of making successive connections between the long sections of the insulated rail and the main insulated conductor is partially quoted in Prof. Ayrton's letter; but, for the information of your readers, I will give the whole quotation (of 12 lines out of a patent of 12 pages), and thus enable them to judge how far the claims put forward can be substantiated by the patent of 1881. The passage occurs on page 15, lines 7-17, and runs as follows:—"Instead of the mechanical plungers shown on sheet 2" (referring only to sectional conductors a mile or more in length) "for automatically connecting the main cable with the section just entered by the train, and for automatically disconnecting the main cable from the section the train is leaving, we may use electric means for this purpose based on the wheels, rollers, or brushes on one side of a carriage, completing the electric circuit through the wheels, rollers, or brushes on the other side, or based on the wheels, rollers, or brushes in the front of a carriage or train being in connection with the insulated section just entered on, whilst the wheels, rollers, or brushes in the rear of a carriage or train are in contact with the insulated section being left, and so connecting for a short time the two insulated sections electrically together; or we may employ a magnetic arrangement depending for its action not on the weight of the train, but on its magnetic mass."

Parenthetically, I may remark that Profs. Ayrton and Perry limited themselves in the above quotation to the application of electrical means of connection to the devices shown in sheet 2, which have all reference to sections "a mile or more in length;" and in their patent 2,395, 1883 (which, it should be noted, is subsequent to mine, 1,791, 1883), this limitation, for good reason, as I shall show, is persisted in.

Dr. Hopkinson took out a patent in October, 1882, No. 4,718, in which he described an electrical method of connecting a sectional rail to an insulated main conductor, that method being based upon the difference of potential produced by the motor of the train acting as a generating dynamo when cut off from the main (on entering an unconnected section). This method Messrs. Ayrton and Perry, in their 1883 patent, claim as being that which they intended to describe in the quotation which I have already given you from their patent of 1881. This is what they say (2,395, 1883, page 21, lines 8-11):—"His (Dr. Hopkinson's) method of actuating the box is that previously suggested by us in our original patent No. 783, 1881, page 15, lines 12–16, and used by us in the method illustrated in Fig. 20 of this specification."

A reference to lines 12-16 on page 15 of the 1881 patent quoted above, will show those of your readers who may not already be aware of the fact, how prone Prof. Ayrton is to read his knowledge of the present into his hints of the past.

To return to the 1883 patent, in it electrical methods of connecting the sectional rubbed rail to the main conductor are shown, the methods of connection depending on a short-circuiting of the main current as the train passes from one section of the rubbed sectional-insulated rail to another. That such a plan

Digitized by Google

could be worked I have no doubt; but it is evident that it could only be applied in cases (as the inventors themselves specify) where the sections are a mile or more in length, as it is only under such conditions that the contact boxes could be subject to the supervision which they would evidently require, on account of the heavy spark which must result in them as a consequence of breaking such short-circuit. The patentees were evidently aware of this objection, for they propose to reduce it by introducing a double winding on to their magnets, one of which shall be of high resistance. The remedy, however, is as bad as the disease; as the self-induction of the high-resistance coil would yield a spark quite as hurtful as the one it is intended to avoid.

I do not claim absolute immunity in my system from sparking; but the small spark which can occur, *is not in the closed contact box*, but at the end of the sectional surface road bar, which is built to withstand hard usage, whether electrical or mechanical. This is effected by the plan of electrically charging each section in advance of the one actually rubbed by the car contact.

Prof. Ayrton is evidently so well acquainted with the various patents which have been granted to me for the application of electricity to tramway working, that he will not be surprised to find that in my patent (No. 1,791, of April, 1883, page 2, lines 12-30), I specify the use of secondary batteries carried by the tramcar to influence, through a magnet also carried by the car, a carrier or contact-maker between the insulated conductor and the sectional conductor, thus anticipating his patent of 1883 by a few months.—Yours, &c., FRANK WYNNE.

5, Westminster-chambers, March 11, 1890.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—I read with considerable interest the report upon the Wynne system of electrical traction which appeared in your issue of the 28th ult., because only about a year ago a model of a system having exactly the same objects and securing the same advantages in a much simpler manner was exhibited at Westminster, and I believe inspected by one of the gentlemen making the report.

This model is at present in Liverpool. It illustrated a system in which a central conductor is laid in short sections separated from each other, the charged section being always covered by the car. There is no slot in the roadway or any obstruction to traffic, while all complicated appliances stowed away in contact boxes under the street are dispensed with.

I mention this as likely to be of interest when read in connection with the somewhat extravagant amount of laudation bestowed upon Mr. Wynne's no doubt excellent system, and to show that "electricians in this country" did not by any means confine their attention to accumulators and slotted conduits, or yet to "overhead conductors."—Yours, &c., C. B. B.

LEGAL INTELLIGENCE.

Chamberlain and Hookham (Limited) v. Cadogan Electric Light Company (Limited).

At the Birmingham County Court on March 5th, before his Honour Judge Chalmers, Messrs. Chamberlain and Hookham (Limited), 4, New Bartholomew-street, Birmingham, electrical engineers, sued the Cadogan Electric Light Company (Limited), 91, Manor-street, Chelsea, Brompton, London, for £31. 10s., the price of two electrical meters. The defendants counter-claimed for £25, loss alleged to have been sustained by failure of the meters to register electricity supplied to customers.

Mr. Hugo Young was for the plaintiffs; Mr. Ruegg for the defendants.

The defendants, on receipt of plaintiffs' circular, advertising the Hookham patent electrical meter as a reliable apparatus, arranged for the loan of a meter, and subsequently ordered two. The meters did not act; complaints were made, and it was found in one case that the armature was out of order, and in the other case that the friction wheel was untrue. Even after being put right the meters did not satisfy the defendants, and when the purchase money was demanded they declined to pay, and now contended that as they had ordered "reliable" meters, and the meters in question were not reliable, plaintiffs must accept a return of the machines and pay damages for loss sustained through their inefficiency.

Mr. HUGO YOUNG argued that this case came under the law governing contracts for well-known merchantable goods, and alluded to decisions indicating that a purchaser who ordered and received a well-known merchantable article could not refuse payment even if the article did not suit his purpose.

Mr. RUEGG argued that the defendants did not know of Hookham's meter till they received the circular; that the meter was not a well-known merchantable article; that the circular and correspondence amounted to an expressed or implied warranty that the meters should be fit for the purpose for which they were supplied. Even with regard to patent articles it would be a good defence to an action that the articles had not met the purpose for which they were intended.

After prolonged argument, his Honour said there was no question that the meters had been ordered, supplied, and accepted. They were patent meters, and had not been invented very long; they were very delicate, and dealt with a highly complicated subject-matter. Probably no perfect meter existed at the present time, but there was no question that under certain conditions the Hookham meters did work well for a certain period. No doubt the meters supplied to the defendants were made and tested in the ordinary manner, and there was no pretence for saying that they met with any accident in transit. Defects were subsequently found, but there was no evidence as to how the defects were caused, and in any case the defects were not organic faults.

Mr. RUEGG relied upon the correspondence and plaintiffs' circular as forming the contract on which the order was given. But it seemed to him that defendants made inquiries, heard plaintiffs' representations as to Hookham meters, and then ordered Hookham meters. If those representations were made honestly—and no doubt they were—they did not amount to a warranty. The circular was an ordinary trade circular. Every inventor issued such a circular, and honestly praised his patent; and so long as the praise was honest and correct, the inventor was not liable under questions of warranty. Still, a man of business, buying a patent article—especially a new article—dealing with a highly complicated subject matter, attempting to solve a problem not hitherto solved, would naturally protect himself by saying, "I will take this on approval, or I must have your specific guarantee for it." That seemed to be the business-like way in which a purchaser would protect himself. If he did not so protect himself, and both he and the seller honestly thought the article would answer the purpose in view, the purchaser must take the risk. There was no express warranty in this case, and there was no implied warranty—the rule *caveat emptor* applied.

Judgment for plaintiffs on claim and counter-claim; execution stayed pending appeal.

Radcliff v. Great Western Railway Company.

At Torquay County Court, on Saturday last, before Judge Edge, Mr. William Radcliff, electrician, Torquay, sued the Great Western Railway Company for 10s., damage caused to Edison Swan incandescent lamps in transit from London to Torquay.

Mr. LAMBERT, solicitor, Paddington, appeared for the Company, and Mr. RADCLIFF conducted his own case. He stated that, when he opened the box containing six lamps, he found the filaments of two broken. A special glass rate had been charged in order to secure safe transit. He attributed the breakage of the filament to jolting.

Mr. LAMBERT, in defence, contended that the lamp in question was a defective one, and that the fact that the glass was not broken showed there had been no negligence on the part of the railway company.

After laying stress on the absence of any notification as to the contents of the box, his Honour non-suited the plaintiff.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Council of the Borough of Brighton will receive tenders for—(*a*) The erection of an engine and boiler-house, with chimney, shaft, and other buildings at the Corporation Electric Lighting Station in North-road, in the said borough; (*b*) The supplying and fixing of two Lancashire boilers: one double-furnace tubular boiler, and one feed water-heater; (*c*) The supplying and fixing of four sets of steam dynamos; (*d*) The supplying and fixing of electrical storage batteries; (*e*) The supplying and fixing of electrical instruments, apparatus, and appliances; (*f*) The supplying and fixing of electrical cables, wires, and protections in certain public streets in the borough; (*g*) The supplying and fixing of street and other boxes, junctions, apparatus, and connections, and apparatus to be used in the distribution of electricity; and the performance of certain other works in connection with the said several contracts. Further particulars will be found on page xv. of advertisements, and all other necessary information can be obtained of Mr. Francis J. Tillstone, Town Clerk, Town Hall, Brighton.

SALES BY AUCTION.—Tuesday, March 25th, is the date fixed by Messrs. Wheatley Kirk, Price, and Goulty for the sale by public auction, on the works premises, 417, Old Ford-road, Bow, E., of the modern engineering machines, tools, plant, and stores, particulars of which will be found on page iii. of our advertisements.

PERSONAL.—We have received a circular announcing that Messrs Mercier, Corlett, and Co. have started business as Electrical Engineers at the Arcade Electrical Works, King-street, Wigan.

Digitized by Google

The firm consists of Mr. Maunsell Mercier and Mr. G. Stephen Corlett, A.M.I.E.E., the latter of whom was for some years manager to Messrs. Sydney F. Walker and Olliver, and has been engaged for some time past in the application of electricity to colliery purposes. Mr. Corlett has carried out a number of successful installations of the electric light both above and below ground, and has had considerable experience in every branch of electrical work. The firm are agents for Messrs. Crompton and Co. (Limited), for Lancashire, North-West Wales, and Westmoreland, and are also sole agents of the same firm for Northumberland, Durham, and Cumberland.

——— Messrs. Girdleston, Tatham and Co. have commenced business as Electrical Engineers and Contractors at 16, Davies-street, Berkeley-square, London, W.

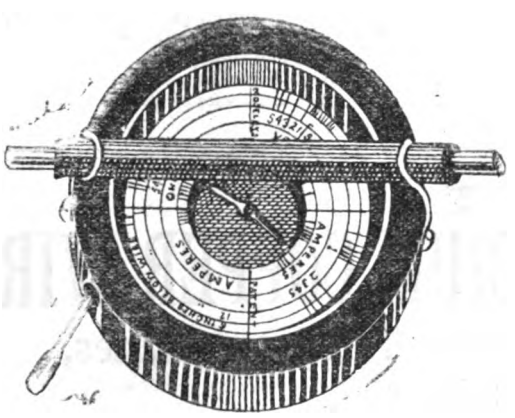
Dissolutions of Partnership.—The dissolution of partnership is announced of Messrs. W. T. Goolden and Co., of Westminster and Halifax, so far as regards S. C. G. Gold.

——— It is also announced that Messrs. Renshaw, King and Co., engineers, of Kidsgrove, Staffs., and Founders' Hall, St. Swithin's-lane, London, E.C., have dissolved partnership.

The Acme Electric Works.—We are informed that this Company has secured the order for making the numerous main and branch distributing switch and fuse boards required for the electric light extension at the General Post Office, and also an order for upwards of 2,000 Cockburn's patent fuse boxes and fuses for use throughout the same installation. Altogether the firm report trade very brisk, amongst the orders on hand being 30 large distributing boards, one of which is to control 5,000 lights.

Britannia Company (Colchester).—We have received Catalogue No. 3 of Engineers' Tools, Amateurs' Lathes, &c., just issued by this Company. The book consists of 104 large quarto pages, and contains illustrations of every description of boring, drilling, surfacing, facing, milling, planing, shaping, slotting, punching, shearing, screw-cutting, dividing appliances, adjustable keys, and similar machines, for which the firm is so well known all over the world. A portion of the book is devoted to descriptions of machines used in electrical engineering shops, particularly electrical engineers' drills; and on page 30 is an illustrated description of a gang of four quick-speed drilling machines, mounted on a cast-iron base, for drilling small holes of varying sizes, or countersinking, recessing, &c. Although the printing of the book is not quite so elaborate as that of some of the catalogues we have recently received, it contains a large number of capital illustrations. Scarcely anything used in engineering shops is missing from this catalogue, which is the most complete of its kind we have seen.

A New Compass Ammeter.—A pocket ammeter in the shape of a compass has recently been brought out by Mr. Walker Moseley. This instrument, which Mr. Moseley prefers to call an electrometer, can be suspended at different distances beneath a conductor, and being fitted with suitably graduated scales provides a ready means of gauging the strength of current flowing in a wire. The illustration, which is quite full size, represents the instrument suspended under a wire. For use as a voltmeter, Mr. Moseley supplies a fixed resistance in the form of a half-disc. The inventor claims that the instrument will perform quite a number of functions, and the low price at which it is sold will no doubt create a considerable demand for it.



International Exhibition of Machinery, Appliances and Inventions.—This Exhibition will open at the Agricultural Hall, Islington, London, N., on March 17th, and will remain open till March 29th. The Exhibition promises to be of an interesting character.

The Rating of Machinery.—The National Society for the Exemption of Machinery from Rating are issuing circulars notifying that the Bill for the exemption of machinery from rating has been ordered for second reading on April 16th. In order to secure the passing of the Bill, the Committee ask that every effort should at once be made to direct the attention of members of Parliament to the importance to all manufacturing centres of the Bill before the House. The question of the rating of machinery has a great interest for the majority of our readers, and we would call their attention to the fact that the National Society are prepared to forward on application forms and requisitions to be used in obtaining influential signatures which will have the effect of fortifying the position of those members of the House of Commons who have taken up the subject. The offices of the Society are at No. 22, Buckingham-street, Adelphi, London, W.C.

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY & HANDBOOK for 1890

The new edition of our well-known Directory and Handbook is now ready. The book consists of 850 pages, and has entailed this year an exceptionally heavy amount of work. The Handbook Division contains a mass of most useful information. The Directory Division consists of more than 400 pages, and contains a very carefully compiled Alphabetical and Classified List of Firms and Persons engaged in the Electrical and Allied Trades in all parts of the world. This Division has been corrected up to date, and the book is thoroughly reliable, even the very numerous changes which take place in the month of January being incorporated. The book is not a mere list of known and unknown Members of Scientific Societies repeated again and again. The Colonial and Foreign Division will be found extensive and reliable. The book has been very favourably reviewed by the Press. The price is 5s. 6d., post free in the United Kingdom.

COMPANIES' MEETINGS & REPORTS.

Liverpool Electric Supply Company.

The annual meeting of this Company was held on Friday last, March 7th at their new premises in Highfield-street, Liverpool; Mr. A. H. Holme in the chair.

The report of the Directors, which the meeting was called to discuss, states that "the amount of net profit available for dividend, including the balance brought forward from last year, is £2,750. 13s. 7d. Out of this sum the Directors recommend the payment of a dividend of 3 per cent., absorbing £2,100, and to carry forward the balance to next year's account. The expenditure on capital account during the year (including a proportionate charge for general expenses) has been £52,957. For a business of this class it is obvious that the capital expended on land, buildings, and plant, must, in the early stages, be temporarily out of proportion to the possible earnings of the Company, as it is necessary to construct the generating stations, and to lay the underground mains on a sufficiently ample scale to meet not only the present but the future demand for the light. For example, the number of incandescent lamps on December 31, 1889, supplied from the Company's stations was approximately 6,400, whereas the mains, stations and plant were capable of supplying double that number. During the year the balance of the Company's share capital has been issued at a premium of 5 per cent. After protracted negotiations with the local authority, the Directors have succeeded in obtaining a Provisional Order for an enlarged area of supply, including Bold-street and other important streets which were not included in the original Board of Trade licence. The position of the Company is very much improved by the Provisional Order, which places its business on a thoroughly satisfactory and permanent basis. The demand for electric light steadily increases."

The CHAIRMAN, in moving the adoption of the report, congratulated the shareholders on the result of the year's working. Although the dividend declared was small, it had been well earned. Fresh arrangements have lately been made with Messrs. Holmes and Vaudrey. By these arrangements the Company secured the services entirely of the former gentleman, while Mr. Vaudrey would give his valuable experience in case Mr. Holmes was ill or not able to attend to his duties. This alteration did not cause any pecuniary difference to the Company. The increased demand for the light was very much in excess of their most sanguine anticipations. Indeed, few companies had come so prominently into public favour as this; hence it was natural to expect competition: but they had completed improvements by which they were enabled to defy competition, with due regard to material and workmanship.

Sir DAVID RADCLIFFE seconded the adoption of the report, which was supported by Mr. JAMES LISTER and Mr. DAVIDSON, and carried.

The retiring directors—Sir David Radcliffe, J.P., and Mr. Vaudrey—were re-elected, as was Mr. W. L. Jackson the auditor.

The meeting terminated with the usual vote of thanks to the Chairman for presiding.

Exeter Electric Light Company (Limited).

An extraordinary general meeting of this Company was held on Tuesday at the Company's works, New North-road, Exeter. Mr. W. H. Ellis (Chairman of the Company) presided.

The SECRETARY (Mr. H. Michelmore) read the notice convening the meeting, which was called for the purpose of considering, and, if thought fit, to pass a resolution to the effect that the Company's Articles of Association be altered by the insertion of the word "ten" in the first line of Article 56, in substitution of the word "seven," so that the article might in future stand as follows:—"The number of Directors shall be ten, or such smaller number (not less than five) as the Directors may from time to time determine."

The CHAIRMAN, in opening the proceedings, remarked that the machinery in the Company's possession was now nearly all paid for, and if they had another engine and dynamo they would then be able to supply the large number of 6,000 lights instead of 3,000 as at present. The cost, however, would be about £2,000, and as the Company was short of capital, he suggested the advisability of shareholders taking up more shares themselves, and also inducing their friends to purchase some. They would then be able to supply the demands they were receiving, and accordingly increase their revenue; because the expenditure in connection with the supplying of 6,000 lights when they secured the additional machinery would be very little more than the cost of supplying 3,000. The Company proposed to add Dr. Woodgates and Mr. Joseph Dalke to the directorate, both of whom had consented to the proposal. He then moved the alteration of Article 56, so that it might in future stand as set out above.

Mr. C. J. B. SANDERS seconded the motion.

Mr. MASSINGHAM, the managing Director, observed that he hoped it was only a question of time—and not a very long time—before the Town Council would see their way clear to light the streets with electricity. They were rivals, but friendly ones, of the local gas company; but, at the same time, he thought they might fairly ask and receive some of the sympathy and consideration which the Corporation had extended to the gas company for so many years.

The motion was carried unanimously, and the proceedings terminated.

The Direct Spanish Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended December 31st last, to be presented to the general meeting of shareholders, to be held on Monday, the 24th inst.:—

1. The accounts for the half-year ended December 31st, 1889, show, after providing for Debenture interest, a balance to the credit of profit and loss of £6,361. 2s. 7d.

2. The traffic receipts are in excess of those for any previous half-year, and show an increase of £1,592. 2s. 6d. as compared with the corresponding half-year of 1888.

3. The working expenses are £690. 10s. 4d. in excess of those for the corresponding period of last year.

4. The Company's cables and the land lines in connection with them have continued in good working order throughout the half-year.

5. Owing to the increase of the Company's business it became indispensable to remove the London telegraph station to more suitable and extensive premises. The Directors have therefore taken on lease No. 74, Gracechurch-street, which has been fitted up so as to meet the development of the traffic, and which was opened for business on July 20th last.

6. Of the balance of profit and loss £2,500 have been put to the reserve fund, which now amounts to £17,515. 19s. 8d., and there remains an available balance of £3,861. 2s. 7d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 6 per cent. per annum (free of income-tax) on the Ordinary shares, making, with the previous distribution, 5½ per cent. for the year 1889, against 4½ per cent. in 1888. This will admit of a sum of £846. 18s. 2d. being brought forward to meet possible contingencies.

7. Mr. Edmund Etlinger and Mr. John Denison Pender are the Directors retiring by rotation, and offer themselves for re-election, The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

The dividend warrants will be issued on April 1, 1890.

NEW COMPANIES REGISTERED.

KEY'S ELECTRIC COMPANY.—Objects: To carry on the business of electrical engineers, mechanical engineers, and manufacturers of and dealers in all apparatus required in connection with the employment of electricity for any purpose. Capital, £15,600, in 3,000 ordinary shares of £5 each, and 600 Founders' shares of £1 each. Of the ordinary shares, 1,500 shall be allotted to John Henry Ward or his nominees, and the remaining 1,500 to Franz Deutsch or his nominees. Of the Founders' shares, 450 shall forthwith be paid up in full in cash. No remuneration to be paid out of assets except for extra special service. Borrowing powers are not restricted. Registered, March 7th, by Tamplin, Taylor, and Joseph, solicitors, 165, Fenchurch-street.

MACMAHON'S PATENT ELECTRIC CHECK SYSTEM.—Objects: To carry on the trade of manufacturers of and dealers in automatic or other machines, instruments, and apparatus of all kinds, adopting therefor an agreement of March 6, 1890, made with Francis Edward Macmahon and Charles Hitchen Ashley, the particulars of which are not specified in the Articles of Association. Capital, £30,000, in £10 shares. First Directors (three to five) Charles Hitchen Ashley, Henry Burt, and Francis Edward Macmahon, holding office until 1893, and their appointees prior to ordinary meeting in 1890. Qualification, £1,000, in shares or stock. Remuneration, £100 per annum each, divisible, however, in proportions to be determined. Borrowing powers are not restricted. Registered, March 6, by Gush, Phillips, Walters, and Williams, solicitors, 3, Finsbury-circus.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended December 31, 1889, and payable on the 25th inst. The books of this Company will be closed from the 18th to 24th inst., both days inclusive. The traffic receipts of the Company for the week ended March 7th amounted to £5,060.

EVERED AND CO. (LIMITED).—This well-known firm of electrical and general fittings manufacturers announce the issue of debentures for £50,000, carrying interest at the rate of 5 per cent. per annum, which will be issued in amounts of £50 and £100, payment to be made in full on allotment. The prospectus states that the issue is made for the purpose of further extending the already large works at Smethwick and in Birmingham. These debentures will form a first charge as a floating security upon all the real and personal property, assets, and effects of the Company (except the uncalled capital). The last balance-sheet of the Company, certified by Messrs. Chatteris, Nichols, and Atkins, shows the assets to exceed £180,000, exclusive of goodwill. Since its formation the Company has paid regular dividends at the rate of 7½ per cent. per annum, and there is a reserve fund of £10,000. The Company's bankers are the London and Westminster Bank (Bloomsbury Branch) and the National Provincial Bank of Birmingham, of whom, and of the Company, forms of application for this new issue of debentures may be obtained.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of February amounted to £19,800. From the 1st January to 28th February these receipts amounted to £39,400, against, in the corresponding months of 1888 and 1889, £41,800 and £42,000 respectively.

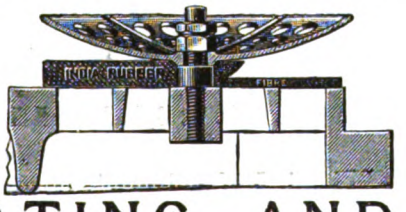
STOCK EXCHANGE.—Application has been made to the Committee to appoint a settling day in and to grant a quotation to the Westminster Electric Supply Corporation, Limited—ordinary shares; and United River Plate Telephone Company, Limited—£146,128 Five per Cent. Debenture Stock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended March 7th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,896.

WESTERN UNION TELEGRAPH COMPANY.—This Company has declared a quarterly dividend of 1¼ per cent.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature
Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.
"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 618.—Vol. XXIV. FRIDAY, MARCH 21, 1890. Price Fourpence.

NOTES.

An Edison "fundamental" patent of considerable importance has just been sprung upon the electrical industry on the other side of the Atlantic. At the beginning of the present month the Edison Electric Light Company commenced an action against one of the companies controlled by the Westinghouse Company for the infringement of Edison's electromotor meter patent of 1881. This patent lays claim to "the combination with an electric circuit, containing translating devices, of an electric motor having a definite loading and apparatus for registering the work done." The motor, it is further stated, may be provided with fans, and the fans may be placed in a vessel filled with liquid. The apparatus which, it is alleged, infringes this patent is the ingenious alternate-current "induction" meter due to Mr. Shallenberger.

The rush for Provisional Orders which we witnessed last summer, and which in a somewhat more moderate form we are probably destined to witness again this year, undoubtedly placed local authorities in a decidedly awkward position. Their natural sense of justice, and, we may add, the Board of Trade regulations, prevented local bodies from assuming a purely negative attitude with regard to the electric light. On the other hand, their suspicion of the capabilities of the intending illuminant and of the financial soundness of many of its sponsors, together with a not unnatural doubt as to whether electricity would pay, did not tend to make Town Councils, Local Boards, and Vestries very favourably disposed towards the erection of central lighting stations, whether municipal or private.

Having admitted, however, that the question is one of considerable difficulty, it might well be asked, what do local authorities exist for, if not to solve fairly and squarely, and in the best interests of the ratepayers the various knotty problems relating to municipal matters which arise from time to time? Now, for local bodies to obtain electric lighting Orders, and then to pass on the powers so obtained to the first comer and divest themselves of all further legal responsibility, is hardly a fair and square solution of the difficulty, nor will it in the long run be to the best interests of the ratepayers. But such, apparently, is the policy which, as will be seen in our Notes column, the Association of Municipal Corporations have urged the Board of Trade to accede to, and which we are glad to see that this Department has firmly declined to countenance. So long as the Board of Trade only gives preference to the applications of local bodies when these local bodies are prepared to undertake the supply of electricity on identically the same terms as ordinary companies, the electrical industry will have no reason to complain; but it would be manifestly unfair to grant privileges denied to joint-stock companies to local authorities engaged in joint-stock enterprises.

The adverse decision recently delivered at Cincinnati by Judge Taft in regard to the use of the single trolley system has been quickly followed by one in its favour. At Albany (N.Y.), where an action was brought by the Hudson River Telephone Company against the Watervliet Turnpike and Railway Company, the judges have decided that the telephone company must "metallicise" its circuits, and have left open for future consideration the question of which party shall bear the expense of this operation. Considering that entirely apart from the disturbances due to the existence of electric railways, the telephone system of any large town would undoubtedly be greatly improved by the adoption of complete metallic circuits, it does not seem to us that in equity any part of the expense of providing an efficient telephone service should be borne by the traction companies. In view, however, of the expenses and uncertainty of the law, it may be anticipated that an amicable compromise on this point will soon be arrived at across the Atlantic.

At the recent Convention of the National Electric Light Association, Mr. Talmage exhibited a novel and ingenious form of electric heater, consisting of a special variety of transformer. It is composed of a straight laminated iron core, around which the primary coil is wound. The solenoid thus formed is completely surrounded by a single turn of very thin sheet-metal, forming a short-circuited secondary circuit. Nearly all the energy supplied electrically to the primary is transformed directly into heat in this thin cylindrical tube, the large surface of which is sufficient to ensure rapid radiation. Heating within the cylinder is avoided as much as possible by using laminated iron cores and employing thick primary wire, although, of course, all the heat there produced is utilised, the efficiency of this kind of converter being necessarily 100 per cent. The heaters exhibited by Mr. Talmage took 100 volts and about 6 amperes in the primary circuit, and developed about 3,000 amperes in the secondary. The temperature attained by the cylindrical sheet is, unfortunately, not mentioned. The only doubtful part of the

Digitized by Google

invention arises from the fact that the insulation of the primary coil must suffer from the high temperature to which it is necessarily subjected, unless the radiating surface of the secondary circuit is very large.

In the current number of *La Lumière Electrique* is described a new method of fixing iron filing-curves, due to M. Korobow. The usual method of fixture, on a plate of glass covered with gum by passing a jet of vapour over the surface, is objected to on account of needless cost and the unsatisfactory nature of the results obtained. The photographic method is, moreover, difficult, and only possible to a comparatively few. M. Mach's process consists in mixing iron filings with aniline powder and spreading over the surface. The figure is formed in the usual way, the iron filings are removed by means of a magnet, and the aniline remains fixed to the paper. The figures obtained are, however, seldom sharply defined. In M. Korobow's process a plate of glass is warmed on the smooth upper surface of a shallow iron chest containing water raised to a suitable temperature by means of a spirit lamp. A piece of paraffin is placed on the glass, and in the course of three or four minutes spreads itself evenly in a thin layer over the surface. The glass plate is removed, the surplus paraffin running off. The image is formed with iron filings on the cooled paraffin, which does not adhere to the iron; so that, if the image is unsatisfactory, the filings may be removed and a new figure taken. To fix the curves, the plate of glass is again placed on the warming stove. Finally, the surface of the paraffin is covered with white paint, so that the curves appear black on a white ground. Very well-defined figures may thus be obtained. A similar though much simpler process consists in covering one surface of stiff white paper with a layer of paraffin, by warming over an iron plate, spreading the filings over the cooled surface, and fixing them with a hot iron or a gas flame.

When Sir William Thomson is led into error he always finds it out himself before anyone else suspects it. These occasions are, however, so rare that they deserve to be recorded. In a note communicated to the *Phil. Mag.* he has endeavoured to show that the quantities of electricity induced in the secondary by the starting and stopping of a current in the primary are not always equal, as is usually supposed. The inductor current on make is generally less sudden than that on break; so that, if the currents do not distribute themselves evenly throughout the conductor, the effective resistance of the secondary is less to the current induced by the make than to that induced by the break. As the quantity induced is inversely as the resistance of the secondary circuit it would therefore appear that the two induced quantities would differ. The reasoning employed would convince nearly every reader; but Sir William Thomson, in the foot-notes, shows that the argument is all wrong, and that the common belief that the two induced quantities are equal is quite correct.

A most striking example of the skin resistance of conductors for alternating currents has recently been noticed by Lord Armstrong, and will be found described in our Notes column. A bar of steel, held in the hand, was accidentally allowed to short-circuit for a moment an alternating current dynamo. The surface of the bar immediately became so hot as to blister the fingers. The heating, however, only occurred at the surface, for the bar just afterwards was found to be quite cold.

Up to the time of going to press our New York letter had not reached us.

Drogheda.—The Corporation, at their last monthly meeting, decided to apply for a Provisional Order.

Belfast.—At the last meeting of the Corporation it was unanimously decided to apply for an electric Lighting Provisional Order.

Académie des Sciences.—At the last meeting of the Académie des Sciences, Lord Rayleigh was elected correspondent to the Physical Section.

Brunn.—The firm of Bartelmus and Co. intend to erect a central station on the Doubrava system (*Electrician*, April 19, 1889, and July 26, 1889).

Madrid.—It is announced by *El Telegraphista Espagnol* that Dr. Celestino Goni and the Director of Telegraphs have founded an electrical engineering college at Madrid.

An Electrical Bakery.—The new premises of Mr. W. Beale, confectioner, in the Holloway-road, London, N., are lighted throughout by electricity. There is also an electrical bakery.

Hong Kong.—The enterprising Californian Chinamen who are about to introduce the electric light into Canton are now considering the advisability of trying to get a long-term franchise to light Hong Kong.

The International Telegraph Congress.—In the Chamber on Thursday last week the Minister of Commerce asked for a vote of 100,000fr. for the International Telegraphic Congress to be held at the Louvre next June.

The Strand Electric Lighting Order.—The Board of Trade has intimated to the Strand District Board of Works that the Strand Electric Lighting Order, against which the Board petitioned, will not be proceeded with any further.

Obituary.—We regret to record the death on the 18th inst., at Seaton, Devon, after a long illness, of Captain Alfred P. Briscoe, who formerly, in the service of the Eastern Telegraph Company, commanded the cable ships "Hawk" and "Chiltern."

Mr. Edison and Mining Investigations.—Mr. Edison, says the *Financial News*, has taken quarters in Charlotte, North Carolina, for himself and assistants. For the next year they will pursue their investigations in the mining districts of the State.

Telegraph Extensions on the North-West Frontier.—A telegraph line is to be constructed between Quetta and Apozai, the head-quarters of the new Zhob Valley district, and in time there will be direct communication between Dera Ismail Khan and Apozai through the Gomal Pass.

Chemical Society.—The anniversary meeting of this society will be held this year on Thursday, March 27th, at 4 p.m. The members and their friends will dine together at the Whitehall Rooms, Hotel Métropole, on the evening of the same day, at seven for half-past seven o'clock.

City of London and Southwark Subway.—Sir Edward Watkin, Mr. Barratt, Mr. Bell, Mr. Perks, and other members of the Metropolitan Railway, visited the works of the City of London and Southwark Subway on Friday last, and expressed themselves pleased with the working of the electric locomotive.

Islington.—At the last meeting of this Vestry the committee's recommendation that the formal consent of the Vestry should be given to the House-to-House Company's Provisional Order, was agreed to, it being at the same time resolved not to approve for the present of the Order promoted by the Brush Electrical Engineering Company.

The Inventor of the Cowles' Process.—We are informed that Mr. Alfred Cowles, whose death was recently reported from Chicago, was a prominent newspaper man in that city, and was the uncle of Mr. Alfred Hutchinson Cowles, one of the inventors of the Cowles' process. The latter gentleman, we are pleased to hear, is in good health.

Digitized by Google

Bath.—Mr. Massingham has been granted an extension of time to June 24th before commencing the electric lighting of the streets. Under the contract with the Corporation the lighting should have been started on the 25th inst. The reason for the delay is said to be the difficulty which has arisen in connection with the laying of the underground mains.

Philosophical Society of Glasgow.—A lecture on "Public Lighting by Electricity" was delivered on Wednesday night under the auspices of this Society by Mr. Henry A. Mavor, in the banqueting hall of the City Chambers, Glasgow. Prof. M'Kendrick presided, and Sir William Thomson was amongst those present. At the close of the lecture Mr. Mavor was accorded a vote of thanks.

New Telegraph Wire to London.—The erection of a new telegraph wire between Aberdeen and London has just been sanctioned by the Post Office authorities. At present there are two duplex Wheatstone circuits for private messages from London to Aberdeen, and two wires devoted exclusively to the transmission of news. The new wire is to be used for private messages, and will be fitted up as a duplex Wheatstone circuit.

Telegraphic Communication between India and China.—There is every probability, says *Indian Engineering*, that in the future a through land line of telegraph from India and China will be opened. Our wires now stretch as far eastwards as Bhamo, and the China Government some time ago had extended their western lines as far as Yung Chang, 30 miles east of Momein in the Yunan Province, and not more than 130 miles from the north-eastern frontier of Upper Burma.

Frankfort-on-the-Main.—Herr von Müller, of Munich, formerly manager of the "Allgemeine Elektrizitäts-Gesellschaft" of Berlin, has been chosen to superintend the work connected with the International Electrical Exhibition to be held in this city in 1891. Herr von Müller, who took a leading part in the Munich Electrical Exhibition of 1882, contributing not a little to its success, will shortly make a tour of Europe in order to personally promote the interests of the undertaking.

Port Said.—A telephone exchange was opened at this place on January 28th last by the Telephone Company of Egypt (Limited), and the chief firms and shipping companies have already given their support to the undertaking, Permission has been granted by the Suez Canal Company for a cable to be laid beneath the canal, and those firms and others having establishments on the East Bank will shortly be placed in direct communication with the Central Office, situate in the Boulevard du Port.

The Telegraph and Telephone in Chili.—In a report from Santiago just issued by the Foreign Office, the British Minister states that, besides State lines, private lines are developing considerably in Chili. The interior of the country is crossed in all directions with a vast network of telegraphic wires. Telephonic communication connects the different suburbs to the principal towns, and even the near villages, and is especially used for communication between offices, factories, and warehouses, and for police service.

Interesting Presentation.—An interesting ceremony took place at the Reindeer Hotel, Newcastle-on-Tyne, on Saturday, March 8th. Mr. J. G. Moon having resigned his appointment of works manager to Messrs. J. H. Holmes and Co., electric light engineers, of that city, the *employés* of the firm, to show their esteem and regret at his leaving, presented him with a very handsome ormolu clock and vases, value £20. We understand that Mr. Moon has accepted the position of works manager to Messrs. J. G. Statter and Co., of West Drayton.

Country House Lighting.—One of the most successful installations of the electric light for private purposes yet carried out in Ireland is that just completed at Grove House, in the county Tipperary, the residence of Mr. R. Burke, Master of the Tipperary Fox Hounds; where the out-offices, stables, and kennels are lighted by electricity, as well as the house itself. This installation was carried out to the specification and under the immediate superintendence of Messrs. J. K. Fahie and Son, of Dublin. Accumulators charged by an Elwell-Parker dynamo are employed.

Telegraphs in Brazil.—There is a prospect that the Brazilian Telegraph Department will shortly be located in truly palatial premises. The central station in Rio have been found exceedingly inconvenient, and the last mail advices report that the Minister of Agriculture had asked the Department of the Interior for permission to have the City Palace for the headquarters of the Telegraph Department. According to the *Rio News* of February 17th, it was expected that the Director-General of Telegraphs will shortly announce a reduction of 20 per cent. in the ordinary rates and of 50 per cent. in the rates charged to the press.

Accident to the Electric Light at a Theatre.—A panic occurred at the Volks Theatre at Vienna on Saturday last, owing to the melting of the insulation of some of the electric light wires. As soon as the molten drops began to fall on the stage the occupants of the stalls started from their seats, but order was restored for a while by the presence of mind of an actor, who went on with his part. Presently, however, a fireman blew a shrill fire signal, which proved too much for the nerves of the audience, and there was a general stampede. Fortunately no one was hurt. It is to be hoped that those responsible will now look to their fuses.

Aden.—On the 7th inst. a severe rainstorm, lasting over three hours, visited Aden, and in less than an hour all the Government tanks, with a total capacity of eight million gallons, were filled and overflowed to the sea in a destructive torrent. All the roofs of the Eastern Telegraph Company's station leaked, and the instrument room suffered terribly. The wires and instruments were all wet and all the circuits were in contact, and it was found necessary to run new temporary connections. On the 14th Aden was visited by another tremendous rainstorm, accompanied by much thunder and lightning. On the 15th there were again heavy showers of rain. While the lightning lasted all the cables were put to earth.

English Telegraphists in Persia.—In the concluding letter of a long and interesting series on "Persia and the Persian Question," which has recently been appearing in *The Times*, the writer remarks: "For 26 years a telegraphic department, with a staff of 40 English officials, working a single wire between Meshed and Teheran, a triple wire between Teheran and Bushire, and a duplicate cable along the shores of the Persian Gulf, has been in existence in that country. It is among the most agreeable incidents of travel upon any of these lines to come at intervals of 60 or more miles upon the telegraph station, occupied by an English official, who dispenses a generous hospitality, and, as a rule, is excellently informed about the country in which he has lived and worked so long."

The Lighting of the City.—At the last meeting of the Commissioners of Sewers a report of the Streets Committee relative to the proposed contracts with the Brush Electrical Engineering Company and the Laing, Wharton, and Down Construction Syndicate was considered with closed doors. The *City Press* remarks in this connection:—"It is almost incredible that even yet the exact form of the contract for electric lighting in the City has not been definitely settled by the Sewers. It is said that clauses have been inserted which will be enforced upon the companies, under the threat of opposing their applications for Provisional Orders. The persistent opposition of a section of the Commissioners of Sewers may possibly run the City into great difficulty and expense; for when the Provisional Orders are obtained the companies are not likely to undertake street lighting on the terms proposed."

Municipal Authorities and Electric Lighting Orders.—In accordance with the resolution passed by the Association of Municipal Corporations, the Town Clerk of Hull and Mr. A. Goring Pritchard, the secretary, visited the Board of Trade last week to arrange for a deputation to the President on the subject of inserting powers in electric lighting Provisional Orders enabling local authorities to transfer their undertakings or delegate their powers to companies. They discussed the question with Mr. Calcraft, the secretary of the Board, and he agreed to amend the Model Order so as to enable local authorities to delegate their powers to companies, but at the same time he declined to divest the local authority of all responsibility. The Model Order will accordingly be revised, and Mr. Calcraft has promised, if it be thought advisable, to arrange for a deputation to see the President on the subject.

Technical Instruction.—The object of the Bill introduced by Sir Henry Roscoe, M.P., is stated as being to clear up any doubt as to the legality of the provision of technical and manual instruction in public elementary schools. At present it is questionable whether the managers of these schools may include such instruction in the time-tables, so that attendance at it may be counted as attendance at school. The effect of the Bill will be to remove all doubts on these points. It declares that the managers of any public elementary school may provide technical or manual instruction for the scholars either on the school premises or in any other place approved by the inspector; and attendance at such instruction is to be deemed to be attendance at the public elementary school. The condition on which Parliamentary grants are to be made in aid of technical or manual instruction in public elementary schools are to be those contained in the minutes of the Education Department and of the Science and Art Department in force for the time being.

Glasgow.—Reports with regard to an accident to a fireman which recently occurred at the premises of Messrs. R. Sorley and Son, jewellers, have been laid before the Corporation. Captain Paterson, inspector of fires, states that while attending a fire in Messrs. Sorley's shop, John M'Gregor, fireman, received a severe electrical shock which necessitated his being off duty for eight days. Mr. Cook, electrician, reports that the fire, and the accident to the fireman, were both due to leakage of the high potential electricity, and that the leakage was caused by the men on the job scamping their work at a place where it was exceedingly difficult of detection. Moreover, the faulty conductors were arranged in contravention of rules issued by the Institution of Electrical Engineers and the Insurance Companies for the prevention of fires. With these exceptions, all the work was well executed, the overhead arrangements conforming fully with the Board of Trade regulations. The Council resolved to forward copies of the reports to the Board of Trade, and direct their attention to the subject.

Electric Bills in Parliament.—The Canterbury Gas and Water Bill came before a Select Committee of the House of Commons on Wednesday. One of the clauses in the Bill proposed to authorise the Company to spend money in going before the Board of Trade to apply for an Electric Lighting Provisional Order. Mr. Harry E. Jones, C.E., the engineer to the Commercial Gas Company, in giving evidence for the promoters, said that if anyone were to give a supply of electricity to the city, no doubt the Gas Company would be able to do it better than strangers. That was also the view, he knew, of electricians, because he had been approached over and over again, owing to his connection with one of the London gas companies, to see whether he could not adopt some method of working with them. He thought electric lighting companies had taken the cream of the lighting from the gas companies. He did not think the two lights competed for general purposes, but only where expenditure was not considered, such as restaurants, hotels, and clubs. He thought, taking London, that electric lighting would be very likely to develope if the gas companies had the right of supply. The Committee were unanimous in saying that it was better to eliminate the electricity clause altogether.

The Resistance of Conductors to Transient Currents.—At the last meeting of the Royal Society of Edinburgh, Sir William Thomson read a Paper recounting an accidental illustration of the effective ohmic resistance to a transient electric current through a steel bar. He said that at the recent meeting of the British Association at Newcastle Lord Armstrong had told him of an interesting incident. A bar of steel about a foot long, which he (Lord Armstrong) was holding in his hand, was allowed accidentally to come in contact with the two terminals of a dynamo. He instantly felt a painful sensation of burning, and he let the bar drop. He found his fingers where they had been in contact with the bar severely blistered. The bar was found immediately afterwards to be quite cold. This proved the outer surface of the steel to have been intensely heated, and that not enough of heat was generated to sensibly warm the whole bar. Lord Armstrong had sent him the bar and some further details. There were two hollows burned out of the metal at the points where the bar touched the terminals of the dynamo. Lord Armstrong had held the bar midway between the two marks. It was perfectly cold three or four seconds after he dropped it. The dynamo gave an alternate-current of 85 amperes, at a difference of potential of 103 volts. Sir William Thomson then showed how the theory involved could be worked out by Maxwell's fundamental equations of electromagnetism. He discussed the theory at some length, and showed that there was a thermal analogy.

Electric Lighting in Japan.—The following is a list of the Electric Light Companies actually in operation in Japan, with the capacity of the various stations and the number of lamps actually in use:—

Companies.	Lamp capacity.	Lamps in use.
Tokio Electric Light Company	12,800	7,500
Kyoto Electric Light Company	2,200	900
Kobe Electric Light Company	2,200	1,000
Osaka Electric Light Company	3,500	900
Nagoya Electric Light Company ...	1,600	700
Total	22,300	11,000

In addition, the following companies have received Government sanction for supplying the annexed number of lights:—

	Lights.
Nagano Electric Light Company	1,000
Kumamoto Electric Light Company	1,000
Nagasaki Electric Light Company	1,000
Hakata Electric Light Company	1,000
Yokohama Electric Light Company	5,000
Hiroshima Electric Light Company.....	1,200
Shidsuoka Electric Light Company.....	1,500
Hokkaido Electric Light Company	2,600
Hakodate Electric Light Company	1,000
Niigata Electric Light Company	1,500
	16,800

The first company to begin operations was the Tokio Electric Light Company, which started in 1886. The extent to which the electric light has been adopted in the Japanese cotton mills is a very remarkable feature of this rapid development of electric lighting.

Dry Batteries for Telephone Work.—Within the last few years a number of dry batteries have made their appearance in America, some of which have met with not a little success, and have been tried to a considerable extent by the telephone companies especially, who find the care which their batteries require to be a considerable item of expense. In discussing the question relative to the advantages and disadvantages of the dry battery over the ordinary fluid cell, Mr. John A. Barrett, without referring to any particular form of dry battery, shows, in a recent article, that, all things being taken into consideration, the dry battery can never compete with the fluid cell for the usual run of work. As he puts it, the amount of water which any cell will contain stands almost alone and independent of the size and form of the electrodes as the limiting measure of the ultimate life of the battery at any work for which it is fitted. The size and form and quality of the electrodes affect the temporary constancy of the cell, but the question whether, in any specified service for which the cell is adapted, it will continue active for one month, or six months, or a year, is answered almost exclusively by the measured quantity of water which the cell is made to contain. Hence, he argues that the life of a dry battery must in any case be inferior to that of the fluid cell. Besides, in the usual form of dry battery when the cell is worked out, it is practically useless for any other purpose, and practically none of its parts can be used over again; whereas in the fluid cells, such as the Leclanché, the zinc may be replaced and the porous cell renewed at a comparatively slight cost. Mr. Barrett points out also that water in a cell is necessary to dissolve the salts formed by the deposition of the zinc, which, if they do not go into solution, soon increase the internal resistance of the dry cell to such a point as to make the cell useless for any practical purpose. As a remedy for exhausted cells of this nature Mr. Barrett suggests washing the porous cup and its contents in dilute muriatic acid. Taking all of this into consideration, Mr. Barrett concludes that except in special situations, such as on board ship or railway trains, where cells have to be shipped a great distance and placed in ignorant hands, the dry battery cannot compete with the fluid cell.

MAGNETISM IN IRON AND OTHER METALS.*—X.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 468.*)

§ 50. **Supplementary Remarks on the Magnetometric Method.** In testing the magnetisation of soft iron, especially if the specimen is at all thick—it will be found necessary to pause after each increase in the magnetising current, and to keep the current constant for some seconds, or even minutes, before the iron takes its full magnetisation. The "creeping up" of the magnetometer deflection which takes place after each increase of magnetising force will be spoken of more fully in a later chapter.

If the specimen is placed rather near the magnetometer and the deflection threatens to become greater than the scale will measure, the magnetometer needle may be brought back towards its undeflected position by using a permanent magnet (a hard steel wire will do well) to counterbalance a part of the the deflecting force exerted by the specimen under examination. This compensating magnet must be placed so that it exerts no force at the magnetometer except in the direction exactly opposite to that of the force the specimen exerts. In other words, it must exert deflecting force, not directing force (§ 39), and to secure this it should be placed before or between the magnetometer (pointing towards it) in the line B A C of Fig. 18. When the compensating magnet is introduced, the number of scale divisions through which it causes the needle to return is to be noted, and this is to be added to subsequent scale readings in reckoning the virtual deflection. The compensating magnet is specially convenient when we wish to examine the effect of applying or removing a small amount of magnetic force when the specimen is already somewhat strongly magnetised.

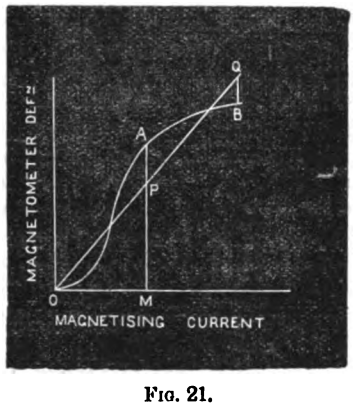

FIG. 21.

A useful method of getting increased sensibility is to use a compensating coil (§ 41) to balance a part (or even the whole) of the deflection produced by the magnetisation of the specimen itself. Suppose, for instance, that it is desired to examine particularly the form of the magnetisation curve under moderately weak magnetic forces—say the part O A B of the curve (Fig. 21)—we may set the specimen near the magnetometer, and at the same time advance the compensating coil so that it counterbalances a large part of the deflection. Thus, let P M be the part of the deflection balanced by the coil, when the magnetising current is O M: the whole virtual deflection is got by adding this to P A, which is the observed deflection. For any stronger or weaker current the part balanced is represented by the corresponding ordinate of the straight line O P Q. The slope of this line is found by observing the deflection given by the coil and solenoid when the specimen is taken out and a known current is applied. When the specimen is put in and the process of magnetisation is gone through, the actual deflections of the magnetometer are, of course, limited to the (positive or negative) portions of the ordinates intercepted between the straight line O Q and the curve. By adjusting the position of the coil so that O Q is nowhere far from the curve a high degree of sensibility becomes possible, for the whole range of the magnetometer scale may then be used in exhibiting the differences P A, Q B, &c. This method should be specially serviceable in dealing with ellipsoidal specimens of moderate elongation.

* All rights are reserved.

§ 51. **The Ballistic Method.**—The ballistic method, briefly alluded to in § 38, was invented by Weber, was used by Thalen, Stoletow, Rowland and others, and received its name from Sir William Thomson.* It determines any sudden change of magnetic induction by measuring the quantity of electricity in the transient current which is induced in a coil wound over the magnetised piece. Let a coil, which for brevity we may call the secondary coil, be wound on the bar or ring or other specimen which is to be magnetised. The coil need not extend over the whole length of the specimen, and in the case of a bar a short coil is best, wound over the central part only, where the magnetisation is most nearly uniform. The coil is to be put in circuit with a galvanometer, the needle of which has a considerable moment of inertia (in relation to the directive force acting on it), so that it swings slowly. An ordinary mirror galvanometer is easily adapted to serve as a ballistic galvanometer by fixing a small weight to the mirror. If the specimen is wound with a magnetising solenoid sudden changes of its magnetism may be produced by applying a magnetising current, by increasing it by steps, by reversing it, and so on; and each of these will cause a "throw," or impulsive deflection of the ballistic needle, which will be proportional to the whole change of magnetic induction within the secondary coil. The "throw" is proportional to the whole quantity of electricity which passes in the transient current, and this in its turn is proportional to the change of magnetic induction within the coil. Let Q be the total number of lines of magnetic induction within the secondary coil, and ΔQ any sudden change which this number undergoes. Let N_2 be the number of turns in the secondary coil, and R_2 the whole resistance of the secondary circuit (in ohms), including, of course, the resistance of the ballistic galvanometer. Then the whole quantity of electricity in the corresponding transient current is

$$\frac{N_2 \Delta Q}{R_2}.$$

The observed throw of the galvanometer measures this, and the simplest way to calculate ΔQ from it is to compare this throw with that which occurs when the number of lines of induction within a coil in the secondary circuit is changed by a known amount. In other words, we may standardise the ballistic galvanometer by finding what throw a known change of induction causes.

§ 52. **Earth Coil.**—Suppose, for instance, that there is included in the secondary circuit another coil, consisting of a number of turns of wire wound on a pretty large frame, and that this is laid flat on a horizontal table, so that it may be suddenly turned over. By turning it over we cause the direction of the vertical component of the earth's magnetic force in it to be reversed, and thus induce a throw of the ballistic galvanometer due to a known change in the number of lines of induction within the circuit, from which it is easy to interpret the throws that are produced by changes in the magnetism of the specimen.

This "earth coil," as it may for brevity be called, was first used in magnetic researches by Rowland.† Instead of lying horizontally it may stand vertically facing towards the magnetic north and south, so that when turned over it will cut the horizontal component of the terrestrial field, or it may be set at right angles to the dip, so that the whole terrestrial field acts upon it. The horizontal or the vertical position is, however, more convenient. For the former a light wooden frame lying on the table answers well. Fig. 22 is engraved from a photograph of an earth coil, which the writer has found serviceable; the coil is wound on a large brass ring mounted on trunnions and furnished with projecting stops, which strike against the post P and allow the coil to turn just 180 degrees. When the post P is standing up, as in the figure, the coil lies horizontally, and the vertical component of the earth's force is then the active field; but the post can fold down by means of a hinge so

* *Phil. Trans.*, Vol. CLXVI., p. 693.
† *Phil. Mag.*, Vol. XLVI., 1873.

Digitized by Google

that the coil stands vertically, and it may then be set to cut the horizontal component.

Let N_1 be the number of turns in the earth coil, A_1 its area in square centimetres, and F the (known) value of that component of terrestrial magnetic field which acts upon it. A sudden reversal of the coil changes the number of lines within it by the amount $2 A_1 F_1$, and the whole quantity of the transient current is

$$\frac{2 N_1 A_1 F}{R_1},$$

R_1 being the resistance of the secondary circuit at the time when the observation with the earth coil is made. It is convenient and generally quite practicable to keep the earth coil continuously in the secondary circuit, in which case $R_1 = R_2$. Let d_1 be the ballistic throw produced by the earth coil, and let d_2 be the throw produced by the magnetic change ΔQ, which we wish to evaluate:

then,
$$\frac{N_2 \Delta Q}{R_2} : d_2 :: \frac{2 N_1 A_1 F}{R_1} : d_1,$$

from which
$$\Delta Q = \frac{2 N_1 A_1 F R_2 d_2}{N_2 R_1 d_1}.$$

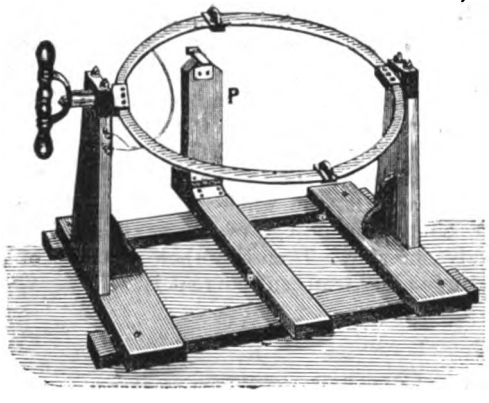

FIG. 22.—Earth Coil for use in the Ballistic Method.

§ 53. **Use of a Solenoid and Current for Standardising the Ballistic Galvanometer.**—To use the earth coil successfully we must know with sufficient accuracy the horizontal or the vertical component of the local magnetic field. These are apt to vary in a rather capricious way within a magnetic laboratory. The following method of standardising a ballistic galvanometer (due, the writer believes, to Sir William Thomson) is a good substitute for the method of the earth coil. The results it gives are independent of variation in the local field, but depend on the absolute measurement of a current. A long magnetising coil is to be uniformly wound on a brass tube or a wooden rod, or some other non-magnetic core, the diameter of which must be accurately known. Over this primary, at the middle of its length, a short secondary coil is to be wound, and put in circuit with the ballistic galvanometer. Let A_3 be the mean area of the primary coil, and n_3 the number of turns in it per centimetre of the length. Then, if a current, C (C.-G.-S. units), is made to pass through it, the magnetic force (or induction) within it (at any place near the middle) is $4 \pi C n_3$ per square centimetre, and the whole number of lines of force (or induction) which the current introduces within the coil is $4 \pi C n_3 A_3$. If N_4 is the whole number of turns in the secondary coil, and R_4 the resistance of its circuit, the quantity of electricity in the transient current that passes when the primary current C is made or broken is

$$\frac{4 \pi C n_3 A_3 N_4}{R_4}.$$

Let d_4 be the throw which this produces, then

$$\Delta Q = \frac{4 \pi C n_3 A_3 N_4 R_2 d_2}{N_2 R_4 d_4}.$$

Still another way of standardising the ballistic galvanometer is to discharge through it a known quantity of electricity, namely from a condenser of known capacity, charged to a known potential. This has no particular advantage over the method already described, and it is less likely to be accurate in practice.

(To be continued.)

ELECTRIC ARC LIGHT CARBONS.

BY O. G. PRITCHARD.

That hitherto we have been unable to cope with France, Austria, Germany, or Bohemia in the production of electric-arc-carbon candles is seen by the fact that our supplies continue to be drawn from Continental manufacturers. Paris claims good makers, such as Carré, Sautter-Lemonnier and Gaudoin, but their prices being high in great measure precludes their adoption on a large scale. Berlin boasts Herr Siemens, Austria Herren Hardtmuth and Schmeltzer, and the Apostle carbon comes to us from Bohemia. These carbons have of late years been much reduced in price, and leave little or nothing to be desired. From America we obtain the Brush carbon, solid and coppered, which eventually we may expect to see superseded by the cored uncoppered carbon. Other large makers also might be mentioned, to whose specialities I need not now refer. Up to the present we stand committed to Siemens, Hardtmuth, and Schmeltzer, who, between them, with the Apostles divide the honours and the profits. Strenuous efforts have been made during the past ten years to introduce a home-made article, efficient and good, but failure alone appears to have waited upon endeavour. This has led to the idea that carbon-candle making can never become an English industry. The writer has, however, produced carbons on a scale of some magnitude which were testified by experts to be quite equal to those of the foreign makers, and he now publishes the whole process employed by him, and the results of eight years' experiments and experience, in the hope that the arc-light carbon industry may eventually become an English one.

The difficulties in the way of producing a perfect carbon, like all other difficulties, vanish with close application to the subject. These various processes, so easily detailed and explained, however, have only been perfected after many years' devotion to the subject and large expenditure of funds. How not to do it is the antecedent to all discoveries, and every inventor, or would-be discoverer of hidden processes, has to learn that only by the continuous registration of negative results can he hope to achieve positive success. I think it will be instructive and also interesting to explain the many faults to which carbons are prone, to diagnose the maladies, and to point out the cause of failure, the necessary preliminary to a cure. The *ultima thule* of carbon perfection, perhaps, has not yet been achieved. Yet I am of opinion that, with the elimination of the faults hereinafter described, a carbon will be produced as near perfection as the severest critic can wish for.

I think we get the carbon and the light in their worst form in the Jablochkoff system. The varying displays of blue, red and yellow, and green lights certainly afford a great choice of colouring, but are undesirable, to say the least. This system, however, being a thing of the past, need not occupy our time. Hissing, also, may now be said to be like the dodo—dead. We come, however, to a serious defect in the little gaseous flame that is sometimes seen to travel round the point of the positive carbon whenever the arc lengthens beyond the normal, and which throws a dark shadow upon the bowl. Also this defect may be enhanced by a faulty lamp not answering quickly to the change in the amount of current, and not allowing the arc to become shortened. This has been attributed to the lamp; but seeing that by removing the carbon, and placing a good carbon in circuit, the effect ceases, the fault must be attributed to the carbon, and upon investigation it will be found to arise from the presence of occluded gases in the body of the carbon. This, again, arises from the improper nature of the material employed, which renders the carbon incapable of receiving or retaining the compression to which it had to be submitted in the press; or it may arise from want of due saturation in an after process, whereby the want of com-

Digitized by Google

pression is got over, and the pores containing these occluded gases are filled with carbonised matter. All or some of these may be assigned as reasons.

But the fault lies in the material employed. I make this statement with boldness, and further assert that the purest carbon is incapable of yielding a good carbon candle, unless it possesses qualities which have to be imparted to it mechanically. The nearest approach which Nature affords for a proper material is gas-retort carbon, inasmuch as the grain is hard, good, and so, well fitted to the purpose. But this material is too impure for use, and is expensive to purify, which prevents its adoption. When the preparation of material is touched upon, this will be more clearly understood. Now, the grain and character of the material, outside and beyond its purity, are matters of moment. By way of more fully illustrating my meaning, let me take the purest lampblack, perfectly suitable *per se* for carbon-making as regards purity, yet, owing to the absence of grain, cannot be made to retain its compression; it occludes gases, and the perfection of the carbon is destroyed, and its life considerably shortened. As far as my experience reaches, I should say that a 10-millimetre carbon (cored positive), 42 volts, 8-ampere current, $\frac{3}{16}$in. arc, gave the highest results. If the arc lengthen to $\frac{1}{4}$in. red flames are produced in the best carbons I have tested.

Conductivity is of the greatest importance, the greater the facility with which the current passes the better the light and the less the E.M.F. required. Thus I think I may state, without experimental data to go upon, but by observation only, that a candle of high conductivity will give as good a light with a 6-ampere current and 38 volts as one of lower conductivity using 42 volts and 8 amperes. Indeed, when the conductivity is very low, the current will not produce the arc, and the carbon becomes intensely heated. This conductivity depends entirely (given pure carbon) on the length of time to which it has been submitted to the firing process. Graphite appears to owe its peculiar condition of high conductivity to its lengthened subjection to Nature's forces, unapproachable by human efforts. Great pressure, continuous and intense heat protracted over long periods, even if possible, would prove commercially impracticable; yet I entertain no doubt that carbon submitted to a white heat, such as would melt wrought iron, for a whole week, would produce a candle more graphitic in character and possessing higher conductivity than one that had been subject to such treatment for a less period. As I deal with the subject of firing, and my special economic arrangements for so doing, this subject will be more fully dealt with.

Again, the duration of the positive carbon is a matter of moment, since it is *de rigueur* that the waste should not exceed 1in. per hour; and as this is now an accomplished fact, it has become a necessity. For some inscrutable reason, foreign makers supply only 10in. positives unless otherwise ordered, so that with 1in. in the holder, and something to spare to save the lamp from heating, little is left besides the 8in. required for eight hours' light. I have met with no material in its native state capable of reducing the consumption to this standard; the prepared material employed by the writer satisfies these conditions.

Another defect, and one which makes the otherwise perfect carbon valueless, is curvature. This takes place in drying and firing. If not properly or sufficiently dried, carbons will not only bend during the firing process, but break into several pieces. The method of avoiding this will find its place further on. With lampblack carbons, fully 50 per cent. will be curved, but with the prepared material described at length, and with proper care taken in the drying, no anxiety need arise. Another matter of grave importance, the consideration of which, if neglected, will lead to most serious results, is the following. A carbon may be selected, placed in the lamp, and found to give perfect results with a normal $\frac{3}{16}$in. arc. Another candle from the same parcel, in the same lamp, gives only a $\frac{2}{16}$in. arc; whilst yet another finds its place of rest at $\frac{1}{4}$in. Now to adjust these varying arcs to produce equal light, the top in one case, and the bottom of the lamp in the other case, will have to be weighted so as to adjust the arcs to a normal length. But when lamps are running in series this constant readjustment becomes impracticable; yet without this readjustment one lamp would be burning properly, another would be burning, but giving a minimum of light, whilst the other would be flaming—each carbon good in itself, but bad when burnt in series. To what, then, is this irregularity to be ascribed, and how is it to be obviated? The answer is simple. The hydraulic press must be fitted with an atmospheric gauge, capable of measuring at every moment the amount of atmospheric pressure to which the carbon matter is being subjected. The best amount of pressure having been discovered, and care being taken that all the carbons shall be made at that pressure, does it not stand to reason that carbons pressed out at 50 atmospheres must give different results to those pressed at 150? And when we hear, as I have heard, that carbons are irregular, and not so good as they used to be, can it not be well understood how a careless workman in charge of the press, receiving a bucket of pugged material, and passing it through the press without taking any heed of the difference in pressure indicated by the gauge, amounting, perhaps, to 20 or 30 atmospheres, vitiates the perfection of the carbon, and does irreparable mischief? The matter lies in the hands of the pressman, who has the gauge for his guide. The man who pugs and prepares the material requires an amount of experience that can only belong to an expert to enable him to grasp a lump of material, and say within 10 atmospheres what the pressure required to pass it through the press would be. Several puggings, and at least three days, are necessary in the preparation of the material. From experience I can say that 120 atmospheres produce good results—nothing under. I have never been able to prepare material requiring a pressure of more than 160; at 120 the carbons leave the press quite warm.

The carbons made by good makers sometimes mushroom. By this is meant the formation of a head resembling a mushroom button upon the extreme point of the negative, which appears to consist of particles of impure matter thrown down from the positive carbon. If this mushroom top increases and does not break off of itself, which it often does, it may touch the centre of the positive cored carbon, in which case the circuit becomes closed and the lamp extinguished. This fault I attribute to impurity of material and the presence of silica, which fastens itself like a glass bead to the point of the negative, and, being a powerful non-conductor, tends to arrest the current. This bead is formed by the electric current searching out the distributed particles of silica in the positive, but without power to vaporise the globule which it deposits on the negative. Pure prepared material is a certain cure.

The lengthening and shortening of the arc, often described as jumping, and which causes the rapid fluctuations in the amount of light, is the characteristic of a bad carbon, badly made with bad material, and owes its existence to a complication of the faults previously mentioned in an exaggerated form.

A word or two upon coppered carbons. Good wine needs no bush, and a good carbon needs no copper. This coating is given to hide a defect; perhaps more than one, since it may be put on to hide a defective surface, whilst a perfect carbon cannot have a bad one. But the chief reason is to get over want of exterior hardness—a very serious fault. Good carbons should be extremely hard on the surface, gradually softening towards the centre, which in the case of cored carbons consists of pure graphite in powder. A carbon insufficiently hardened (hardness being only acquired by repeated saturation and carbonising) burns to a lengthened cone. This is due to the air rushing in to supply the vacuum formed, and which, meeting with little resistance, disintegrates the carbon, and works it to a lengthened cone, presenting only a small point to support the arc, the light in consequence becoming seriously diminished.

Preparation of Material.

Those who desire fuller information upon the nature of graphite, the various parts of the world in which it is discovered, and other details, may peruse "Spon's" with interest. Two kinds are known, the amorphous and the foliated. The amorphous is quite unsuited to our purpose, and contains often only 45 to 50 per cent. carbon, the rest being argilaceous matter. The foliated under careful test has shown as high a percentage of carbon as 99·679. Crucibles and pencils are made of the amorphous. The foliated graphite which comes to us from

Digitized by Google

Ceylon can be readily obtained in any desired quantity from the Mincing-lane brokers, at prices varying from £16 to £22 per ton, and is well adapted to our purpose. It comes to us in the form of nodules, which require careful selection, and breaking under the hammer in small pieces to extract any quartz discoverable. After careful hand-picking, the graphite must be ground to a fine powder in a mortar or pug mill. After this, the powder should be placed in cast-iron mortars or crucibles, and mixed with chlorate of potash in the proportion of 18lb. of graphite to one of the chlorate, and sulphuric acid (sp. gr. 1·8), 2lb. to 1lb. of graphite. This mixture must be moderately heated until the last fumes of the chlorous gas are evolved, and then allowed to cool, when the excess of sulphuric acid should be decanted. Upon this sulphated and oxidised mass pour a small quantity of fluoride of sodium, stir well together, and after the chlorous vapours have passed off, the hydro-fluoric acid set free by the combination of the sodium with the sulphuric acid will convert any silica present into a gaseous fluoride of silica, which passes away in vapour and leaves the mixture pure. This mass should afterwards be thrown into water and well washed, placed again in crucibles, and submitted to a red heat in a furnace. This will cause the whole mass to swell and disintegrate, forming a light flocculent powder floating on the surface, which must be collected and dried. This impalpable powder is yet unsuited for carbon making. A cutting sharp grain must still be imparted to it, and to arrive at this the thin flat plates of gas-retort carbon, taken from the top of the retorts, must be taken and ground fine, in the proportion of one of gas carbon to three of graphite, with which it must be well incorporated in the initial stage, so that its impurities may be equally eliminated. You cannot obtain these thin carbon plates without purchasing the heavier and impurer shoulder-pieces. However, the refuse may be economically employed in furnace heating, as it gives great heat and possesses great durability.

The material so far prepared must be thoroughly dried, and pugged with sufficient caramel or carbonised sugar, mixed with water, to make a moderately stiff paste, placed in ovens or crucibles, and thoroughly carbonised. A material is thus produced possessing all the requisites desirable. It is perfectly pure, and when ground fine possesses a sharp-cutting grain and great hardness, allowing the molecules under pressure to combine to the exclusion of occluded gases, which allows of a perfect homogeneity which could not be otherwise attained. It will be necessary to crush these lumps so prepared in a stone crusher, and after crushing grind them in a mortar mill, passing the powder through a rotary sieve, working from the counter-shaft, having 90 meshes to the lineal inch, or 8,100 to the square superficial inch. In my next article I shall continue with the method of preparing the above for passage through the hydraulic press.

(To be continued.)

THE INSTITUTION OF ELECTRICAL ENGINEERS.

SOME POINTS IN DYNAMO AND MOTOR DESIGN.*

BY W. B. ESSON, MEMBER.

(Continued from page 477.)

12. Load Diagrams.

A dynamo having been completed, its performance should be recorded in such a manner that we shall be able to tell at a glance what a machine of similar carcase dimensions will under any circumstances give. First, the machine is run on open circuit, and the relation between the ampere-turns on the magnets and the E.M.F. established. In Fig. 20, the curve A B shows this, abscissæ giving ampere-turns, and ordinates the E.M.F. While running at the same speed, take the greatest permissible current from the armature, and, keeping this constant, take observations of the magnetising force and E.M.F., the field being weakened down step by step until it is just possible by adjustment of the brushes to run without sparking. For each reading the brushes will have been adjusted to the sparkless position, and the curve expressing the relation between the magnetising force and E.M.F. when the maximum current flows may be plotted as at Q H. The curve stops at H, because with a further weakening of the field a non-sparking position cannot be obtained. Repeat the experiment for a less current in the armature, then for a smaller still, until there is a series of curves—Q H, E F, C D—as shown, representing the relation between the magnetising force and the E.M.F. for several different values of the ampere-turns on the armature. It will be observed that as the ampere-turns on the armature get less the curve can be carried lower, or, in other words, we can weaken the field to a greater extent before arriving at the sparking point.

This load diagram tells us everything we wish to know about the magnetic circuit of a machine having these particular dimensions, and about the interference of the armature on the field circuit. It tells us the ampere-turns required for any induction on open circuit, or, in other words, the magnetising force required for the shunt only if the machine is to be compounded; it tells us how many ampere-turns must be added to raise the E.M.F. by a required amount with any current flowing, or to compensate any armature load; it tells us how we can over-compound the machine; and, lastly, just how far we can weaken the field for any load without producing sparking. That we can by its aid calculate with accuracy the windings of any machine which requires the same carcase, will be sufficiently obvious without farther explanation.

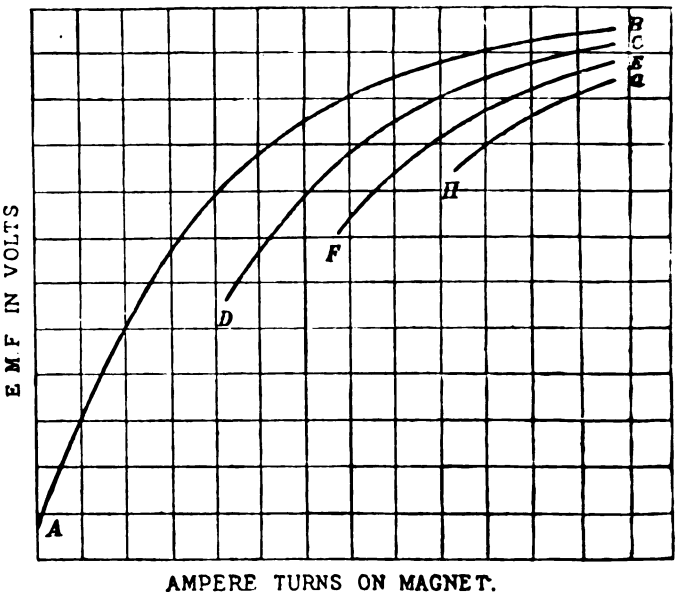

Fig. 20.

13. The Best Relation between the Iron and Copper in the Armature

It is of some importance to know the best relation between the thickness of the iron core and the depth of the winding which will give in armatures the best results for given dimensions. Suppose we have a cylinder armature of certain radial depth over the winding: while keeping this depth the same, we may vary the iron and copper of which it consists within wide limits. The question is, what relation of copper to iron will give the best results, premising that, however the relation is varied, the temperature shall remain the same? The cooling surface we will take to be unaltered, and this means, neglecting hysteresis—for a reason given presently—that the heat generated in the winding shall be constant. Since the waste is constant, the point of maximum efficiency coincides, then, with that of maximum output. If the copper on the outside of the armature is considered as a shell of t thickness, we may, within the limits of our inquiry, take the current that may be carried to generate the same heat $= \sqrt{t}$. The E.M.F. produced will be proportional to the radial depth of the armature core r, and assuming in each case the same degree of saturation, the greatest output for a given radial depth of armature is obtained when $r \sqrt{t}$ is a maximum. This occurs when the exterior layer of copper is about one-fourth the depth of the armature core, the output for different proportions between iron and copper being shown by the curve, Fig. 21. In the diagram the base line A B represents half the radial depth of the armature over the winding, distances measured from left to right giving the thickness of the exterior

* Read before the Institution on February 20, 1890.]

Digitized by Google

shell of copper. The ordinates represent the output. A dotted line, C D, is erected at the point of maximum. It may be assumed, without any great error, that the weight per unit length of circumference is constant, however the proportions vary, so that the curve may be taken to represent maximum output for a given weight as well as for given dimensions. With a square or bar winding this is about correct.

It will be observed that the relation of copper to iron can be varied considerably without making much difference to the output. An armature, for instance, in which the core is six times the thickness of the copper, gives the same efficiency as one in which the relation is 2·75, and the output is in each case only 3 per cent. below the maximum. The relation for greatest efficiency is quite independent of the degree of saturation to which the core is carried, or the temperature at which the machine is worked.

The effect of hysteresis is to reduce the height of the ordinates, and to displace the point of maximum efficiency to the right. The current which can be taken from the armature is a little greater than $\sqrt{t}$, on account of the heat from hysteresis diminishing as the core is reduced in thickness. But, imagining that in all cases the core is saturated to the same degree, the difference in the amount of heat generated from this source is, within the limits of practice, so small a percentage of the whole that its effect on the shape of the curve may be quite neglected.

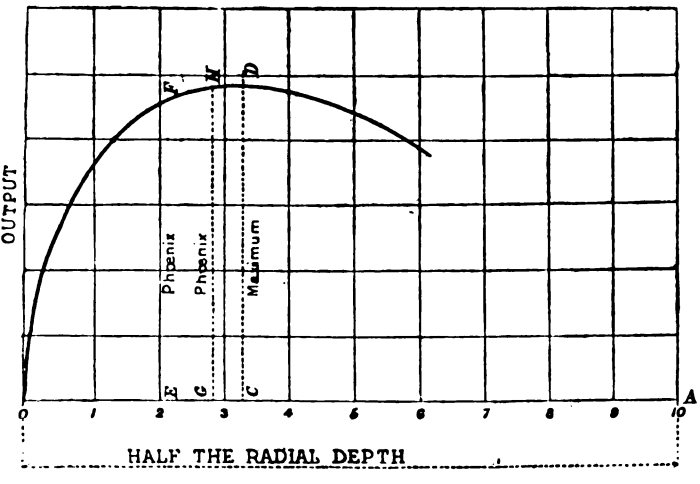

FIG. 21.

Machines are not always designed so that the proportions give maximum output, since other considerations arise besides that of the best result from the armature considered by itself. The question of magnetising the core has to receive attention, and the question is resolved into, What is the best proportion for the machine, considered as a whole? The answer to this depends entirely upon the design. In the Phœnix dynamos we work between the limits given by the two vertical dotted lines E F and G H, in Fig. 21, finding that there we obtain the best results. If we worked to the right we should get a greater output, we should have a greater air-gap, a diminished flux through the armature core, but, on account of the increased stray field, about the same flux in the magnets. The magnetising force and the compensating turns on the magnets would be increased somewhat, while the cross induction would remain about the same. As regards this last point, it is worthy of note that the tendency to sparking, with the usual clearance spaces, remains about the same for considerable variation in the proportion of copper to iron. Increasing the copper does not increase the length of the air-gap in the same ratio, but in a ratio rather greater than $\sqrt{t}$, or than the current which can be taken from the armature. At the same time the radial depth of the core is diminished, the final result being that $\frac{A_2 w}{l r}$ is about constant within the limits of practice.

For drum armatures the relation for maximum output can be similarly determined, and similar conditions fix the limit of departure from the maximum. One point with reference to these considerations should be noticed, and that is, that neither for cylinders nor drums does the point of maximum efficiency or output coincide with the point at which $\frac{\text{watts}}{\text{weight of copper}}$ or $\frac{\text{volts}}{\text{yards of copper}}$ is a maximum, and that these ratios, as applied to compare the performance of dynamos, are accordingly misleading. Given a limiting temperature, the only factors upon which the commercial value of machines should be based are cost and commercial efficiency. Whether the magnets shall be made of wrought or cast iron, whether there shall be a large amount of copper or a small amount, are questions for the manufacturer to decide. In some cases it may pay him to increase the copper and use cast iron, in other cases diminish the copper and use wrought iron. But the finished product is to be judged by its cost to purchase and its cost to run.

14. MOTOR-DESIGNING.

These considerations naturally bring us to the subject of motor-designing, about which there has been expressed from time to time a good deal of difference of opinion. From the preceding section it will be perceived how far we can go in the direction of getting an increased output from a given weight of armature; and it will have been understood from Section 4 that with somewhat lighter field-magnets and a reduced saturation in the armature, a larger yield can be obtained for the total weight, though smaller for the weight of the armature itself. As a general rule, the question of weight does not enter into dynamo-designing, except in so far as cost is affected, and a lighter machine means a somewhat increased cost for the output. But in motors it is sometimes necessary to keep the weight as low as possible; and the point to be emphasised here is that in designing light-weight motors we proceed upon lines precisely similar to those adopted in designing light-weight dynamos.

It has been asserted that in motors the armatures ought to be larger compared with the field-magnets than in dynamos; and by "larger" must be meant either that the armature cross section is greater, or that the ampere-turns on it are more numerous. As regards the former, it has been shown in Section 4 to what extent the relation between the cross sections of the armature and fields influences the dynamo; and the same reasoning applies to motors. As regards the latter, curiously enough, the examples which I have given in Tables II. and III. show no overloading, but about the same number of ampere-turns is carried as by dynamo armatures—a fact which does not favour the "large armature" school. My own experiments with series machines, in which the brushes had equal lead and trail when running as dynamo and motor, seem to show that the difference in the E.M.F. generated under these two circumstances is negligible. In Table IV. are given the results.

V_1 = Difference of potentials at terminals as generator.
V_2 = Difference of potentials at terminals as motor.
C = Current, in amperes.
R = Resistance of machine in ohms.

The cores of the Gramme and Pacinotti armatures were constructed of iron washers separated from each other by paper; while the Bürgin armature consisted of a series of hexagonal rings made of iron wire, each forced on to a six-armed gun-metal spider. The small differences in the last column may be readily accounted for in the case of the Gramme and Pacinotti armatures by errors of observations, as several things had to be measured simultaneously; but no allowance for errors can account for the difference in the case of the Bürgin machine. I talked over these experiments at

Digitized by Google

the time with Mr. Kapp, who suggested that the difference might be due to parasitic currents arising from imperfect lamination, the forcing of the hexagonal ring on to the spiders bringing the wires of the core into actual contact at the corners. When the currents are flowing in the same direction through the machine, the armature rotates with reference to the field in the opposite direction of course as generator and motor. Now, apart from the question of parasitic currents, with an irregularly formed armature like the Bürgin—and the Brush with its eight or twelve projections would come in the same category—one is not surprised at a difference in the E.M.F. ; the wonder would be if the direction of rotation did not alter the field. But with a Pacinotti ring in which the slots are many and close together, the influence on the field is slight, and with smooth Gramme armatures the field is not affected by the direction of rotation at all, so we get the same E.M.F. produced as generator and motor. It must be remembered that the effect of the armature current on the field in cylinder machines is by no means small, as will have been observed by the number of compensating turns required to neutralise it. A machine having 13,500 ampere-turns on its armature would have about 20,000 on its field-magnets, out of which about 4,500 are compensating turns. I mention this to show that the results in Table IV. were not obtained from machines in which the armature effect was negligible, or anything approaching it. The saturation of the core was about 17,000 C.-G.-S. units.

If a machine is run at the same speed as dynamo and motor, provided the currents in the fields and armature are similar, it will always have a higher efficiency as a motor. If E is the E.M.F. generated by the machine, C the current (imagine it series-wound), and R the resistance, the electrical efficiencies as dynamo and motor are in the ratio of $\frac{CE - C^2R}{CE}$ to $\frac{CE}{CE + C^2R}$, the latter being the greater quantity. If we designate all the other losses save that due to the resistance by p, then for the commercial efficiency we have $\frac{CE - C^2R}{CE + p}$, and $\frac{CE - p}{CE + C^2R}$. If p had the same value as C^2R, the efficiency of dynamo and motor would be similar ; but since p has always a lower value than C^2R, the motor has still the advantage.

15. Constant-Potential Motors.

Now, as regards another thing which we have been told sometimes —that the armature and magnet fields are added in a motor—so far is this from being the case, that, under the usual and proper conditions of a trail on the brushes, the weakening of the field due to the current in the armature may play a most important part in the governing of motors at constant speed. In an article contributed to *The Electrician* in 1886,* I hinted at this, saying, "By reason of the current in the armature reacting to weaken the field, does not a shunt motor contain within itself the germ of self-regulation, which, by suitable proportion, may be made effective without a series coil at all?" Since that date motors have been constructed in which the truth so foreshadowed has been realised.

As already stated, the E.M.F. of a separately excited dynamo is represented by an inclined line, C D, Fig. 15, the inclination showing the weakening of the field produced by the current in the armature. Run as a motor, with a trail equal to its lead as a dynamo, the E.M.F. generated—called in this case the back E.M.F.—will be the same, being greater, therefore, as the current is smaller, and smaller as the current is larger. A shunt motor connected to mains at a constant difference of potentials has its magnets excited by a constant current, and the back E.M.F. varies in this way. Its value, calling E_1, the difference of potentials at the mains, is $E_1 - CR$, and it is, of course, proportional to the induction through the armature and the speed. Generally we require the latter to be constant, so we write,

$$n \propto \frac{E_1 - CR}{N_1},$$

where N_1 is the resultant induction through the armature due to both fields. As we have seen, N_1 is not a constant : there is a weakening of the field proportional to the current ; and for N_1 we can substitute a value, $N - f(C)$, where N is the induction on open circuit, and $f(C)$, that function of the current which represents the weakening effect. Writing

$$n \propto \frac{E_1 - CR}{N - f(C)},$$

it is perfectly obvious that if CR bears the same relation to E_1, as $f(C)$ bears to N, the speed, n, will be constant, and quite independent of the load. Referring to Fig. 15, the height, O C, may be taken as representing the induction when the motor is running with no load ; the sloping line, C D, giving the induction for various currents in the armature. The horizontal line, C E, will represent the induction due to the field-magnets alone, and also the difference of potentials at the mains. If the speed be constant, the length of ordinates between C D and C E represents $f(C)$, and also C R. We see clearly that if the induction is diminished without a proportional reduction of the back E.M.F., the speed will increase ; while, on the other hand, if the back E.M.F. goes down without a corresponding decrease in the induction, the speed will be reduced. If it is found that the speed increases as the motor is loaded—and I have seen this—the field must be strengthened, and the turns on the armature reduced, or the armature resistance increased. If the speed gets less, an opposite course must be taken. A shunt motor, then, will run at a constant speed on a constant-potential circuit without compound winding or any other device, if the armature-field and magnet-field are properly proportioned. A position can generally be found for the brushes where the sparking between the load limits is inappreciable, and the motor may be then trusted with perfect confidence to run at a constant speed.

It must not be thought that because a motor transmits power it is necessary to manipulate electro-mechanical equivalents until we get torque in pound-feet or foot-pounds per revolution, or some other mechanical quantities. This is only a waste of time. In designing a motor, we know the horse-power or watts to be given off on the brake at a certain speed, and if we make the machine run at the proper number of revolutions, and in accordance with the conditions of electrical supply, the torque will come out all right without our troubling about it. Suppose we require W watts to be given out on the brake by a motor working on a constant-potential circuit. The power which must be converted in the armature is greater by a certain amount, p, absorbed in friction of journals and brushes, magnetic friction, and parasitic currents. This amount can be foretold to a certain extent, but may be derived from experiments made with machines of the same kind. The power converted being then $W + p$ watts ; the back E.M.F. being settled as determined by the waste allowable in the armature, the current $= \frac{W + p}{E}$ is obtained ; the procedure in design now being exactly as for a dynamo to give a current of $\frac{W + p}{E}$ amperes by E volts at the same speed. If these conditions are fulfilled the torque may be left to itself.

16. Constant-Current Dynamos.

There seems to be an impression that dynamos for high differences of potentials cannot be worked successfully with Gramme commutators ; the reason for this opinion being, I suppose, the breakdown of some imperfectly-constructed machines. That there is no difficulty with the insulation between the conductors and armature core is obvious from the fact that high-potential alternating-current machines are working successfully with armature sections similarly disposed ; the fault appears, therefore, to have been solely with the commutators. I need only reiterate the remark I made here a short time ago—that there is no difficulty whatever in constructing Gramme machines up to 1,000, 1,500, or even 2,000 volts, provided the designer knows what he is about. Many such machines are to be seen in daily work. Mr. Bogue, of New York, gives me particulars of a Wood dynamo manufactured by his company which gives 9·6 amperes, and a difference of potential of 2,640 volts at its terminals ; Mr. Henrion, of Nancy, constructs Schuckert machines of 1,000 volts ; Messrs. Immisch and Co. have constructed motors as well as dynamos of 1,000 volts ; while Messrs. Paterson and Cooper have a large number of machines running at voltages varying from 800 to 1,500. The latter run without sparking at the brushes, and with perfectly smooth commutators.

Several attempts have been made to compound machines for constant current, all of them uniformly unsuccessful. It is beginning to be realised that—Deprez notwithstanding—it cannot be accomplished, and during the next six years the equations for constant-current compound winding may finally disappear from our text books. But it may take longer.

The method of regulation about which I have to make a few remarks is that of rotating the brushes on the commutator, which has proved very successful in some of the machines to which it has been applied. You need scarcely be reminded that if a series-wound machine is directly belted to a separate engine, the combination is almost self-regulating, such small correction as is required being easily effected by a solenoidal electrical governor. In such cases the speeds of both engine and dynamo vary as the E.M.F., but generally this arrangement is not permissible, in consequence of several machines being driven from the same countershaft ; accordingly, some device for regulating at constant speed has to be adopted.

In machines in which the current is variable we endeavour, as I have said, to make the self-induction as small as possible, and we work with the brushes somewhere between the polar tips where the field is almost neutral, or only of strength sufficient to overcome the slight effect of self-induction, and bring the current up to its

* Review : "Electric Transmission of Energy," by Gisbert Kapp, *The Electrician*, Vol. XVII., p. 131, 1885.

Digitized by Google

normal value before the section leaves the brush. In constant-current machines we work always in the active field under the pole-pieces, and to prevent the flow of an enormous current in the section short-circuited by the brush, considerable self-induction has to be given. Consider an armature in the field (Fig. 16). Opposite the parts marked N and S the induction through a section is *nil*; at A and B it is 16,000, 17,000, or 18,000 C.-G.-S., as the case may be—that is, in the machines we have been speaking of hitherto. If we had here a uniform distribution of field over the poles an attempt at constant current regulation by movement of the brushes would only result in sparking, since in every position the back E.M.F. of self-induction is different. If the induced E.M.F. were in one position balanced by the E.M.F. of self-induction, in other positions it would be over-balanced or under-balanced. Another point is, that if regulation is attempted by working with the brushes partly between the polar tips and partly under the poles, the weakening effect of the armature current on the fields is subject to great variation; accordingly, the poles should be extended until the brushes are under them in every position. The essentials for successful regulation will now be apparent. First, the self-induction should balance the field in every position of the brushes; secondly, the poles should be extended so that the brushes in every position of working are under them. An examination of the curve, Fig. 1, will show that up to an induction of 12,000 or so the co-efficient of self-induction is, roughly, constant; so that an armature core saturated to this degree would have the same E.M.F. of self-induction for a constant current, whatever the position of the brushes. In the Wood dynamo already referred to the induction in the armature is 13,000 per square centimetre, and in the Sperry dynamo, which hails from Chicago, it is about 14,000. Mr. Sperry's remarks I give in full in the Appendix, also those of Mr. Bogue concerning the Wood machine. In both these machines the masses of iron in the magnets and pole-pieces are disposed so that the field is fairly uniform over the poles; but this is by no means necessary, provided the E.M.F. of self-induction balances the field in every position. Making the field distribution uniform, and the self-induction uniform, affords the easiest method, however, of attaining the end in view. It remains only to say that the field of the short-circuited section is greatly reduced in strength by the current in the armature, and that the best number of turns per section must be determined by experiment. It will be evident that the single-magnet type of machine as illustrated in Fig. 7, is the least suitable for constant current; and while in America they choose the best form of magnet for the purpose right away, in this country the attempts at regulation have been made very often by selecting the worst form and chopping away at the poles until it comes about right.

It is unnecessary to describe the various forms of apparatus for shifting the brushes. Briefly, they consist of a mechanical device, electrically controlled, whereby the brushes are moved forwards or backwards on the commutator as the current rises or falls slightly. Upon the rapidity with which this regulator responds to variations in the current depends the successful working of the machine. If the current is allowed to rise or fall outside a small percentage, the adjustment of the fields is thrown out of balance, and sparking results. The importance of having a regulator which is sensitive, and acts with promptitude, will therefore be apparent.

17. Relation of Size to Output.

Great differences of opinion exist about the relation of size to output in dynamos. Prof. Thompson, in his "Dynamo-Electric Machinery," quotes several writers who give the output at figures varying from the square to the fourth power of the linear dimensions; and the subject has been discussed to some extent in this room. Mr. Kapp has worked out the relation; and assuming that in larger machines the space taken up by the insulation is proportionally less, more copper being accordingly got on the armature, he makes the output for a machine whose linear dimensions are increased n times from n^3 to $n^{3\frac{1}{2}}$, the speed being inversely as the linear dimensions. Prof. Ayrton thinks it ought to be higher than $n^{3\frac{1}{2}}$, while Dr. Hopkinson finds that, everything considered, it comes out about n^3. With the single exception of Dr. Hopkinson, I am not aware that anyone has mentioned *the* consideration which, above all, determines this relation—that is, the interference of the magnet and armature fields.

If the armature of a machine is lengthened, the electrical work which can be performed by it is increased in proportion. The magnetising force and the ampere-turns on the armature remain the same, and the forward and cross induction bear to each other the same ratio. Here the electrical work for the same number of revolutions per minute is proportional to the weight of the magnetic system, and rather more than proportional to the total weight. The surface velocity of the armature is of course unchanged. Let all the linear dimensions of the magnetic system be increased n times. The length of each component of the magnetic circuit being n times longer, the magnetising force must be n times greater for the same degree of saturation, the total forward induction having n^2 times its former value. The copper on the armature being n times thicker, the ampere-turns which may be carried to raise it to the same temperature will be $n^{\frac{1}{2}}$, and the output, therefore, at the same number of revolutions per minute, $n^{3\frac{1}{2}}$, the E.M.F. being n^2. If the speed is inversely as the linear dimensions, the output is, obviously, $n^{2\frac{1}{2}}$. Now, in increasing all the linear dimensions—the air gap in proportion—we have increased the tendency to sparking. The lengths of the cross circuits are n times longer; consequently, for n times the ampere-turns on this armature, the ratio of the cross induction to the forward induction would be as formerly. But we have put on it $n^{\frac{1}{2}}$ ampere-turns, and the air gap must be therefore increased in the same proportion, in order that the tendency to sparking may be neutralised. Under these circumstances the magnetising force will be greater than n; but, taking into account the increased air gap, and the increased compensating ampere-turns on the magnets, the weight of copper on these will not be greater than n^3; and this amount we can afford to have on a machine in which the other weights are increased in similar ratio. It appears, then, that, with due regard to the balance of the magnet and armature fields, the output is not quite proportional to the weight, if the surface velocity of the armature remains the same, but that for similar machines it increases as the $2\frac{1}{2}$ power of the linear dimensions. Of course this depends to a great extent upon the original machine. If the armature of this is under-loaded, it may be quite possible in the larger machine to take advantage of the condition that less space is taken by the insulation, and so load it to a greater number of ampere-turns than $n^{\frac{1}{2}}$; but if the balance of fields is to be the same in each, $n^{\frac{1}{2}}$ represents the permissible ratio of ampere-turns. It will be found, I think, that where the output increases directly as the weight, the surface velocity of the armature is in the larger machines greater.

With these remarks I bring this somewhat lengthy contribution to a conclusion.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, March 21st.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: "The Villari Critical Point of Nickel." By HERBERT TOMLINSON, F.R.S. "Bertrand's Idiocyclophanous Prism." By Prof. SILVANUS THOMPSON, D.Sc.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Electro-magnetic Radiation." By Prof. G. F. FITZGERALD, F.R.S.

SATURDAY, March 22nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Electricity and Magnetism." By the Right Hon. Lord RAYLEIGH, F.R.S.

MONDAY, March 24th.

SOCIETY OF ARTS.

8 p.m. CANTOR LECTURE IV. 2: "Some Considerations concerning Colour and Colouring." By Prof. A. H. CHURCH, F.R.S.

TUESDAY, March 25th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Paper to be discussed: "Lough Erne Drainage." By JAMES PRICE, Jun., M. Inst. C.E. Paper to be read, time permitting: "Barry Dock and Railways." By JOHN ROBINSON, M. Inst. C.E.

WEDNESDAY, March 26th.

SOCIETY OF ARTS.

8 p.m. Ordinary meeting. Paper to be read: "Carriage Building and Street Traffic in England and France." By G. N. HOOPER.

THURSDAY, March 27th.

CHEMICAL SOCIETY.

4 p.m. Annual meeting.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read: "Alternate *v.* Continuous Currents in relation to the Human Body." By H. NEWMAN LAWRENCE, Member, and ARTHUR HARRIES, M.D.

FRIDAY, March 28th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Foam." By the Right Hon. Lord RAYLEIGH, F.R.S.

SATURDAY, March 29th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Electricity and Magnetism." By the Right Hon. Lord RAYLEIGH, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java Labuan Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo, 5s., postage extra.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which is still further enlarged and improved (making 850 pages), is NOW READY. Orders should be forwarded at once to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.

GOOD FRIDAY.

In Good Friday Week "THE ELECTRICIAN" will be published on Thursday morning (April 3), instead of on Friday (April 4).

Contributors, Correspondents, and Advertisers are requested to take note, and to forward their communications as early as possible, but not later than Tuesday night in Good Friday week.

THE GOVERNMENT AND THE TELEPHONE BUSINESS.

In the House of Lords, on Friday last, the Duke of MARLBOROUGH, who has on former occasions taken the Government to task with regard to overhead telephone and electric lighting wires, preferred a more specific demand for information as to what was intended to be done this year in respect to the owners of the first-named class of wires—that is to say, he wished the Government to make it speedily and publicly known whether they intended to purchase the interests of the Telephone Companies, placing them under the management of the Post Office; or, failing this, whether they would transfer to the companies the unrestricted powers of erecting wires now legally exercised exclusively by the Post Office. Lastly, he wanted to know whether, in the latter contingency the Post Office would confer those powers—or, rather, would refrain from conferring them—on more than, at most, two rival companies. The noble Duke received no definite answer to any of these queries; but it may be safely assumed, without any

DORMAN AND SMITH,

Electric Light

ENGINEERS; MANUFACTURERS

To all the Principal Contractors.

BRAZENOSE STREET, MANCHESTER, ENGLAND

E. P. & W. BALDWIN,

Works:—WILDEN, near STOURPORT.

MANUFACTURERS OF

PURE CHARCOAL SHEET IRON, SUITABLE FOR ELECTRICAL PURPOSES.

London Agents: BROOKER, DORE & CO., Corbet Court, LONDON, E.C.

INCANDESCENT LAMPS

FOR SHIPPING AND EXPORT.

LAMPS OF ALL VOLTAGES & CANDLE-POWERS

FITTED WITH ANY FITTINGS.

The Quality and Durability of these Lamps can be attested by Users and Customers during the past Three Years.

Prices.—For Lamps of between 5 and 25 c.-p., any Volts or Efficiency, including Fittings of any of the usual makes, Cases, Packing and **Free Delivery** in the United Kingdom and many other countries, from **1s. 11d.** to **2s. 6d.** each, according to quantity.

For further particulars and Samples address—

C. J. ROBERTSON,

100, ALDERSGATE STREET, LONDON, E.C.

BRITISH ASSOCIATION STANDARD SCREW THREAD

TAPS, SCREW PLATES, DIES, GAUGES, &c. ($\frac{1}{4}$ to $\frac{1}{32}$ in.),

SUPPLIED BY **TH. LEHMANN,** Original Maker to G.P.O.

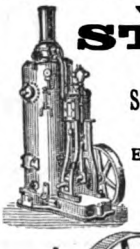
38, HAMPSHIRE STREET, TORRIANO AVENUE, LONDON, N.W.

E. S. HINDLEY,

ENGINEER.

London Show Rooms and Stores— 11, QUEEN VICTORIA ST., E.C.

Works— BOURTON, DORSET.



STEAM ENGINES

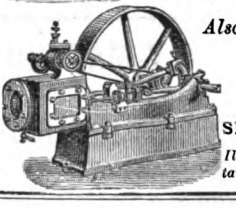
HORIZONTAL, VERTICAL, PORTABLE AND FIXED.

SPECIALLY SUITABLE FOR ELECTRIC LIGHTING PURPOSES.

Small Engines for Installations of 6 20 c p. and upwards.

ECONOMICAL TO USE. MODERATE IN PRICE.

These Engines are controlled by E. S. HINDLEY'S new Governor, which maintains a perfectly uniform speed under sudden variations of work, and is adjustable when working.



Also **STEAM ENGINES**

FOR ALL PURPOSES.

SAW BENCHES,

PUMPS.

SHAFTING, PULLEYS, &c.

Illustrated Catalogues, Photos, and detailed Information free on application.

ADDRESSES.

LAING, WHARTON, & DOWN, 82a, NEW BOND- STREET, LONDON, W., Electric Light Engineers & Contractors. Sole Operators for England of the Thomson-Houston system of Arc Lighting. Special Agents for the Edison-Swan Co.'s Incandescent Lamps and Apparatus. Manufacturers and Suppliers of every requisite for Arc or Incandescent Lighting, Dynamos, Lamps, Switches, Electroliers, Brackets, &c. Specialities in Primary Batteries for Electric Lighting, Venetian Shades and Glass, Carbons, &c. Temporary lighting on any scale at short notice. Estimates free. Telephone No. 3602.

JULIUS SAX, Electrical Engineer and Electric Light CONTRACTOR, RIDGMOUNT STREET, STORE STREET, LONDON, W.C.

Established 1855.

Specialities—Electric Bells, Burglar Alarms, Fire Alarms, Watchmen's Clocks and Fire Indicators combined, Water Gauges, Billiard Markers, Electric Vanes, Lightning Conductors, Speaking Tubes, Gas Lighters, Electrical Testing and Telegraph Instruments, Electrical Torpedo Apparatus.

Automatic Call Bells for Fire Stations, &c., fixed at all Stations under the control of the Metropolitan Board of Works.

Cell Calls for Police Stations, Prisons, &c., as devised for and adopted by H.M. Home Office. Contractor to H.M. Post Office and War Office.

Electric Lighting—Domestic and Public. Estimates Free on Application. Eight Prize Medals awarded.

Telephone No. 3848. Telegraphic Address: "*Sax—London.*"

WALTER T. GLOVER & CO., Electric Wire and Cable Makers, SALFORD, MANCHESTER. Works: Bridgewater-street, Broughton-road, Salford; Salford Electric Wire Works, Salford; Springfield-lane Cable Works, Salford. Established 1868. London Address, 10, Hatton-garden, E.C.; Telegram, "Phonoscope," London; Telephone No. 6691. Manchester—Telegram, "Walter Glover," Salford; Telephone No. 1187.

Specialities—Glover's patent covered Gutta Percha Wire for Leading-in, Tunnel, and Underground Work. Specially covered Iron and Copper Wire for Aerial Lines. Fancy covered single and Double Copper Wire (Paraffined) for Telephonic and Bell purposes. All classes of Silk and Cotton covered Wires for Instruments and Dynamo Machines, Glover's Patent Electric Light Leads and Cables for the various systems.

All descriptions of Covered Wire and Cables for Telegraphic, Telephonic, and Electrical Work, as supplied to the Post Office and the principal Railways, Electric Light, and Telephone Companies.

ADDRESSES.

LAURENCE, PARIS and SCOTT, Limited, Electrical ENGINEERS and CONTRACTORS, GOTHIC WORKS, KING-STREET, NORWICH. Dynamos, Motors, Automatic Cut-Outs, Back Current Cut-Outs, Excess Alarms, Multiple Switches, and Switch Boards. Complete Electric Lighting Plants. Central Station Plants. Estimates on Application.

PHILLIPS BROS., Electrical Wire Manufacturers, The Lea Telegraph Works, HACKNEY WICK, LONDON, E., late of Macintosh-lane, Homerton. Established 1870. Telephone No. 5422.

Specialities—Gutta Percha, India Rubber, Compound, Cotton, Silk, Flexible Cords, Telephone Wire, &c., &c. Multiple and other Wires. Special Wires for Dynamo Machines. Electric Light Leads, &c. Patent Non-Inflammable Insulation for Incandescent and Arc Lighting and Dynamo Machines.

THE LONDON ELECTRIC WIRE COMPANY, ANCHOR WORKS, PLAYHOUSE-YARD, GOLDEN-LANE, LONDON, E.C. (Late of Wenlock-buildings, Ironmonger-row, E.C.)

Specialities—Covered Wires of all descriptions for Electrical Instruments, Dynamo Machines, Bell and House Work, &c. Fancy Paraffined Wires specially prepared for Telephone and other indoor connections.

JOSEPH BOURNE and SON. Works: DENBY POTTERY, near DERBY. London: 6, ST. PANCRAS STATION. Manufacturers of the well-known Stoneware Telegraphic Insulators and Battery Jars. Brown Stoneware. White Stoneware. Brown Porcelain. Porous Cells. Economy, strength, durability, and perfect insulation combined. Prize Medal, Paris Electrical Exhibition.

Makers of Mr. Slater Lewis's Patent Self-Binding Insulator.

J. G. STATTER and CO., Limited, Engineers, ALLIANCE ENGINEERING WORKS, WEST DRAYTON. London Offices, Prince's Mansion, 68, Victoria-street, Westminster, S.W. Dynamos and Motors for all Purposes. Perfect Constant-Current System of Arc Lighting. Estimates free. Write for Lists.

PATERSON and COOPER, Electric Light and Power and Telephone Engineers. EUROPEAN WORKS, POWNALL ROAD, DALSTON (Near Haggerston Station). Contractors to H.M. Government, Leeds Corporation, &c.

Specialities—Phœnix Dynamos, Pilsen, Phœnix, and Clark-Bowman and J. F. Arc Lamps, Cardew's Voltmeter, Paterson's Electromagnet Am- and Voltmeter, Ayrton-Perry Am- and Voltmeters, Wallace Diamond Carbons, Switches, Safety Junctions, and Fittings for Arc and Incandescent Lighting. (Removed from 76, Little Britain, since Nov. 16, 1885)

question at all, that the indiscriminate competitions which he seems to apprehend will never be permitted by the present or any other Government of this country. Nay, further, it would be contrary to the policy hitherto pursued, and manifestly contrary to public convenience, to permit the competition of even two companies over the same area; for although this is a power held in reserve for the protection of the public against the arbitrary action of any one company, its application would be attended with very great evils, foremost among which would be the destruction of that unity of system upon which so much of the convenience of telephony depends. So great, indeed, is this advantage that probably the Post Office has long ago discovered that its nominal right to start competition itself, or to depute it to other hands, is practically inoperative.

As regards competition on the part of the Post Office, it has never taken the business in hand to any considerable extent; and the faint show of rivalry which was exhibited in the west and north of England last year, and which excited much trepidation among the companies at the time, does not appear to have been persevered with. And what it will not do on its own account we may be sure it will not offer to anybody else, and would probably not be accepted if offered, for the reason that competition would be a very hazardous experiment on the part of any new comer. The Duke of MARLBOROUGH and his clients may, therefore, make themselves easy on these points, though we doubt if there is much comfort to be derived from the assurance. It only narrows the issue to a rather painful alternative, that of letting the companies entirely alone, granting them no more powers than they possess at present, and demanding the same, or even heavier royalties; or, of taking advantage of the expiring patents to drive a hard bargain, and get the whole business into Government hands. Almost certainly the expressed intention of the Postmaster-General to review the terms of the agreement between him and the companies at the first opportunity will be acted upon; and the answer of Lord BALFOUR on the part of the Government last Friday plainly indicated that the relations between the two parties were even now under serious consideration. He went on to say, further, that large questions of private right were involved, urging this as a reason for not making them a subject of Parliamentary inquiry at the present stage. This language about private right may or may not be significant of what is taking shape; but, on the other hand, the statement that the more proper course to pursue was to wait till the Government made up their minds and placed their proposal before Parliament in due form, may be taken as evidence that nothing yet has been decided.

This being the position of affairs, it behoves the companies to bestir themselves to meet a crisis in their career which, for good or evil, will speedily overtake them. They must make up their minds, on their part, as to what they really want, and endeavour to enlist sympathy on their behalf by taking the public into their confidence. At the present moment there is as much uncertainty as to what the Telephone Companies really desire, as to what the Postmaster-General really intends. We only repeat what is notorious when we say that a good many people suspect that the companies wish above all things to be bought up by the Government. For our own part we have no opinion on the subject one way or the other; but we do think that if the companies desire to continue their existence it is about time they made the fact generally known. They have an excellent case if they care to present it in a genuinely argumentative form; but, as we have never yet seen anything like a good case set forth on their behalf, it seems no part of our duty to frame one for them. Either they have done their best for the public with the means at their disposal, or they have not; either they have earned their title to a further lease of life, or they have not. Of course, the public are not satisfied on these points; the public never are; but, failing any appeal to them for a more favourable view of their obligations, the companies cannot be surprised if a verdict adverse to their pretensions is given by default.

There remains only one other matter to comment upon in the short discussion which took place in the House of Lords on the occasion here referred to. It seemed to be taken for granted by the Duke of MARLBOROUGH that the telephone, if utilised to its utmost extent, would seriously impair the receipts of the telegraph service. The companies, who rather pride themselves upon it, are mainly responsible for the prevalence of this impression. All the same, we believe it to be a complete mistake. Mr. SCUDAMORE, when asked if he had taken into account the probable loss of postal revenue consequent upon the cheapening of telegraphic communication, replied that he had only thought it worth while to reckon on the probable gain. Similarly it may be said of the telephone, that the increase of facilities in one direction will multiply the employment of them in the other. No diminution of telegraphic receipts is perceptible due to competition of the telephone or any other cause. The receipts from the telegraph are steadily increasing; and if telephonic business increase, so to a like extent, and for similar reasons, will telegraph business. On the Continent this fact seems to have been taken into account by the several Continental Governments—notably in Austro-Hungary and Scandinavia, where the trunk lines are worked by the State, the local exchanges remaining in private hands. Possibly some such compromise may be brought about in this country; but the subject is highly conjectural, seeing that the trunk lines are the least certain of being profitable to anybody that takes them in hand; and for the present, therefore, nothing remains but to imitate the Duke of MARLBOROUGH, who, failing to extract any useful information, good-humouredly consented to wait until the Government made up their minds.

REVIEWS.

Electric Light: its Production and Use, Embodying Plain Directions for the Treatment of Dynamo-Electric Machines, Batteries, Accumulators, and Electric Lamps. By JOHN W URQUHART. (London: Crosby, Lockwood, and Son.)

This is the third and enlarged edition of a work concerning which there can be but one opinion. Since its first issue in 1880 it has been revised, partly re-written, and brought well up to date. The writer is clear in his arrangement, his description possesses a lucidity in keeping with the title of the book, and the illustrations, which are freely scattered throughout, are both accurate and intelligible. Batteries, dynamos, lamps, carrying-systems, appliances, fittings, details of cost and measurement, are all faithfully dealt with, and the text is interspersed with practical directions, hints as to construction, &c. The author states the efficiency of the chief systems, and informs the reader where typical instalments of these may be inspected in actual use; at the same time their respective merits are calmly discussed without prepossession or prejudice. The book may be further described as a complete directory of the more important patents, and as a miniature *vade-mecum* of the salient facts connected with the science of electric lighting. It is essentially of an elementary character, and may be commended to the young electrical engineer, who will find it a convenient hand-book. By the ordinary lay-student of electric lighting Mr. Urquhart's guidance may also be accepted with confidence. The subject has been dealt with historically, and the reader will find the complete evolution of modern electric lighting carefully traced out.

MORGAN'S AUTOMATIC SYSTEM OF ELECTRIC SIGNALLING.

A public demonstration of the system of automatic electric signalling, due to Mr. Frank E. Morgan, of New Haven, Connecticut, was given on Tuesday afternoon, at the Westminster Palace Hotel. The system devised by Mr. Morgan for police signalling resembles in some respects the one which was recently tried by the metropolitan police at Islington, and which was introduced into this country by the Public Safety Signalling Association.

The apparatus at the police-station comprises a receiver, a transmitter, a telephone, and a switchboard. The receiver is arranged so as to be started from any spot where a local substation is provided, and to automatically indicate both the point of origin of the message and its nature. In connection with every police-station it is proposed to erect similarly equipped sub-stations; and at the demonstration on Tuesday these substations were located in a special form of street lamp-post; each of these lamp-posts being provided with a visual alarm-signal, actuated from the central office. It is also proposed to provide special keys to responsible citizens, by means of which they can raise an alarm when necessary; practical joking being in some measure guarded against by the fact that these keys are marked and cannot be withdrawn from the keyhole in which they have to be inserted until the door of the lamp-post is opened by a policeman. A further development of the idea is, for a small annual sum, to provide householders with a transmitting apparatus connected direct to the central office in the same manner as the street posts.

The receiver has a dial face, on the outer edge of which are arranged numbers corresponding to the numbers of the street posts, while on the inner edge there are various printed messages. The current from a street post releases a catch, sets the apparatus in motion, and in the space of a few seconds the two pointers on the face of the receiver point respectively to the post from which the current was sent, and the nature of the message transmitted. The transmitting apparatus is also of the dial pattern, but is only provided with messages. When it is desired to speak to a street post it is necessary first of all to cause a policeman to come to the spot. To effect this a plug is inserted into the numbered hole on the central office switchboard corresponding to the post it is proposed to communicate with. This brings a powerful current into play, which actuates an electro-magnet at the substation, lighting the gas and raising a red cover. The pointer on the transmitter dial is now set at whatever message it is desired to send, and a crank is moved forward to close the circuit, and the message is transmitted. Means are also provided for leaving a permanent record at the central office of the visits of an officer to his post.

Mr. Morgan's apparatus, it will thus be seen, provides for every likely requirement of the police. That some such system of automatic signalling would be a valuable aid to the police authorities goes without saying; and the question of its adoption depends entirely on its ability to stand the rough test of everyday work, and on its cost.

This system, which has been introduced into this country by the Morgan Automatic Electric Signal System Syndicate, would obviously, with a modification of the messages on the transmitters and receivers, be of service in large hotels, &c.

THE PRACTICAL WORKING OF THE ELECTRICAL SUBWAYS OF NEW YORK CITY.*

BY WILLIAM MAVER, JUN.

(Concluded from page 478.)

Electric-Light Cables in Subways.

In the electric-light service in the subways, and I am aware that it is around this that the greatest interest centres, there are, exclusive of the Edison system, four different types of insulation used—namely, the Bishop Rubber Compound, the Standard Underground, the Safety Insulated, and the Cobb Vulcanite Paraffin cables. All these cables are lead-covered.

The Standard Underground Cable.—The insulation of the Standard Underground Cable is obtained by first wrapping thick cotton thread or cord around the wire to any desired thickness. The wire thus covered is then placed in a cauldron of boiling insulating compound—a product of petroleum. This treatment displaces any moisture that may be in the cotton thread. After the cotton has been thoroughly saturated with the compound the whole is then lead-covered. Care is of course taken by soldering up the ends of the cable to prevent absorption of moisture in shipment and in drawing into the ducts. There are now in actual service for electric-lighting purposes in the New York subways over 95 miles of this cable, carrying currents of an E.M.F. of from 300 to 3,000 volts, including many 1,000-volt alternating circuits, and an additional 50 miles of the same cable will shortly be in operation.

The "Safety" Cable.—The insulating material of the "Safety" cable is an india-rubber compound. It differs somewhat, I believe, from the ordinary run of india-rubber compound cables in that the compound is placed over the wire, without seams or laps of any kind. This compound is vulcanised to a moderate degree of hardness sufficient to prevent decentring of the heavy conductors which it insulates, but yet it retains a high degree of flexibility. The thickness of insulation used in No. 4 Brown and Sharpe wire —·204in. diameter—is ·108in. The weight of this conductor, lead-covered, is 4,861lb. per mile. A special thickness of this insulation was made in one instance in response to a call for cable to withstand a strain of 7,000 volts for arc lighting. The thickness of the insulation was ·238in. The conductor is No. 4 B. and S. gauge. This cable is now in the subways. Its length is about three miles. I am not aware that it has yet been called upon to withstand the prescribed 7,000 volts. There are now over 65 miles of the "Safety" cable in actual use in the subways assigned to electric-light circuits carrying continuous and alternating currents of from 1,000 to 2,500 volts E.M.F., and about 15 miles additional are now being placed in subways.

The Bishop Rubber Compound Cable.—The Bishop Rubber Compound Cable is of the well-known Silvertown type. There are two sizes of this cable in the subways—namely, No. 4 B. and S., and No. 6, B. and S. The thickness of the insulation is $\frac{4}{32}$in.; the thickness of the lead covering is $\frac{5}{64}$ of an inch; the outside diameter of the cable is ·65 of an inch, and the weight of the cable is about 3,432lb. per mile. There are of this cable, in successful operation, about 10 miles assigned to alternating currents of 1,000 volts, and five miles to arc circuits of 2,500 to 3,000 volts E.M.F. Double this amount of this cable will soon be laid for similar purposes.

The Cobb Vulcanite Paraffin Cable is of a somewhat unique design. It differs materially in one respect from the other cables described, in that the conductor is freely movable within its insulating medium. The cable is made in practically the following manner:—A vulcanite tube is first made in lengths of about 300ft. This tube is moderately flexible. The tubing is vulcanised in boiling paraffin. The wire is then threaded through the tube, after which the sections of tubing are jointed together. A thick cord is then wound spirally around the vulcanite tube. The whole is then lead-covered, and the space between the vulcanite and lead formed by the spirally wound cord is filled with paraffin. There are about 25 miles of this cable in the subways.

In the case of the Bishop, Safety, Cobb, and Patterson cables, the lead is alloyed with about 3 per cent. of tin. The lead covering of the Standard Underground cable is unalloyed, but it is covered with a thick cotton braiding soaked in "P and B" paint (the latter a product of petroleum), which, it is claimed, will protect the lead from acid gases, &c., and the braid also acts to protect the lead from mechanical injury. All of these cables are guaranteed by the manufacturers for three years.

Condition of the Cables.

It is over a year since current was turned on the first high-tension electric-light circuit in the New York subways. This was a circuit in 125th-street, belonging to the Harlem Electric Light Company. The insulation resistance of the cable, as measured just before the turning on of the current, showed it to be 1,750 megohms per mile. A test made of the same circuit last week, after one year's continuous service, showed it to have an insulation resistance of 1,516 megohms per mile. Since the installation of the circuit just referred to, electric-light cables of the various types described have been drawn into the subways almost as rapidly as they could be manufactured, and test made of the conductors months after the initial test has shown them to be in the same electrical condition as when first laid. There have been several burn-outs in cables in the subways within the year, but with the exception of an abandoned type of cable, to which I shall refer later, these burn-outs have been traceable in every case to de-

* Abstract of a Paper read before the American Institute of Electrical Engineers, New York, February 18, 1890.

Digitized by Google

fective joints or to mechanical injury. In all, according to the best obtainable information, there have been, exclusive of those in the abandoned cable, but five burn-outs in over 185 miles of electric-light wire during a period ranging from one month to thirteen months. In the case of 27 out of 34 of the electric-light circuits in the subways, not a single defect of any kind has occurred since they were placed in the ducts.

Defective Cables.

In the case of the cable previously referred to as having been abandoned, the burn-outs were of almost nightly occurrence. This was a lead-covered cable with a vulcanite tube as an insulating medium. This special cable has, I believe, been abandoned, and is no longer in service in the New York subways. What may appear a singular feature in connection with the burn-outs in this cable was the fact that the cable had a higher apparent insulation resistance than any other cable in the subways, and would frequently on a test show an insulation resistance of over 4,000 megohms per mile a few hours before the occurrence of a burn-out. The same cable showed even a higher test at the factory, namely, about 20,000 megohms per mile. In the latter case it was tested with 400 volts. Burn-outs on this cable have occurred when the pressure employed on the circuit did not exceed 600 volts. The explanation of this may be that, owing to the nature of the insulating material and to the fact that it was not tested under water before being lead-covered, there may have existed fractures in the vulcanite tubing, or such fractures may have been caused in process of drawing the cable into the ducts. Under the tests made with the 100 and 400 volts E.M.F. of the testing battery, a fault would not develope; under the high electromotive force of the dynamo and the current of 10 or 12 amperes the fault would develope. This explanation is apparently confirmed by the fact that 25 miles of a somewhat similar cable, namely, the Cobb cable, which I have described, but in which paraffin is placed between the lead covering and the vulcanite tube, has been in successful operation in the subways for high-tension currents for over two months without any indication of a defect having occurred. It was rather unfortunate that the cable which I have said has been abandoned as unsatisfactory, and which has indeed been withdrawn from the subways, appears to have been the only cable used for electric lighting purposes in the New York subways which came to the notice of an English electrical engineer during a flying visit to this country, and a description of which cable he presented to our sister society in London in a recent Paper, with a favourable prediction as to its probable success.

Locating Faults.

No attempt is made to locate faults in electric-light circuits in the subways by electrical measurements, for the reason that the obstacles in the way of obtaining accurate data are so numerous that it has not been considered expedient to rely on the results of such measurements.

Durability of Cables.

Concerning the much-discussed question as to the relative durability of rubber compound and fibrous cables, I do not think sufficient time has elapsed in the case of the cables in the New York subways to enable one to arrive at a definite judgment. In the case of both types of cable, as I have already said, many circuits have been running continuously for over nine months, and in some instances for over one year, without a defect of any kind, electrical or mechanical, having occurred; and the slighter defects that have occurred on other circuits have as yet been so few in either type of cable as not to certainly show any marked superiority of one type over another. As regards the question as to which kind of cable will best withstand the heat from steam pipes adjacent to the subways, it would appear thus far that the lead-covered fibrous cable is superior to the homogeneous cable not lead-covered. Lead-covered rubber compound cables have not as yet been tried in the heated districts.

Multiple Cables.

There are no concentric cables in the subways in this city. The mains of multiple arc circuits are operated in separate lead covers in the same duct. It is contemplated, I believe, by some of the companies to use one lead cover for such circuits hereafter. One objection on the part of the companies to the use of concentric cables is the anticipated difficulty in making joints, especially where frequent connections for distribution are required. This objection should not hold good in the case of the feeder portion of the circuits. As to the use of multiple cables for electric lighting, one such cable, a fibrous cable having eight conductors under one lead cover, was placed in the subways, but has not been operated as yet, trouble having been found in making perfect joints. I have no doubt that with the experience since had in joint-making, this difficulty would be overcome; but it seems to be the general opinion that the use of multiple cables is not advisable in electric lighting. On the subject of loss due to increased electro-static capacity or to increased self-induction of conductors in the subways, I may say that I have made careful inquiry of superintendents of stations where the alternating current is used, and learn that no perceptible difference in the operation of the circuits as compared with similar circuits overhead is noticeable. I have been informed that in wet stormy weather a decided improvement is observable—in fact, that the condition of the weather does not affect the circuit. This will be the more readily understood when it is stated that a recent test, made during the prevalence of a drenching rain storm, of an arc circuit in the subways four miles in length, showed an insulation resistance of 2,400 megohms per mile. The lamp connections were disconnected from the cable proper during the tests, so that all the terminals of the entire cable were under cover except at the pole.

Joints.

When it was urged upon the electric light companies of this city that they were not using due diligence in placing their wires underground, the companies retorted that they were doing so as rapidly as possible consistent with good workmanship, and they cited the fact that it was not possible to joint up the cables more rapidly than was being done with the number of capable jointers at their command. To this an official of the city replied that this did not, in his opinion, constitute a valid excuse while so many poor men were idle who would be only too glad to be given work at jointing the cables. This was the view of a layman; but it would seem that in a number of instances in the electric light service in this country a similar view, namely, that any one could make joints and that any kind of joints might be made, was held by those who should be supposed to know to the contrary. In this city I think it is now fully recognised, by the electric light companies at least, that it pays to employ good jointers in underground work.

Several forms of joints are used on the electric light cables in subways. The Cobb people make a special joint somewhat as follows:—The ends of the conductors are spliced in the usual way, a hard rubber ferrule having first been placed over one end of the conductor, and a brass ferrule over the other conductor above the insulation. A machine like a double vice is then placed over the lead covering of the cable, and made fast thereto. A tightening device next draws the ends of the vulcanite together, taking up slack in the cable. The vulcanite sleeve or ferrule is then welded by heat to the vulcanite tube, after which the brass ferrule is drawn over the tube. A mould is then placed around the joint, into which molten lead is poured, thus casting a solid lead sleeve. This is quickly cooled by the application to the mould of cold water. The mould is then removed, and the joint is complete. This form of joint has been found satisfactory, I believe. The joint chiefly used on the Standard Underground Cable is made differently from the foregoing. After the conductor has been spliced as usual, and the lead covering has been cut back from the insulation, a few turns of tape are passed around the splice. A leaden sleeve is then put on over this and wiped firmly to the lead cover of the cable. When this has been done, a couple of small holes are punctured in the lead sleeve, through which a boiling insulating compound used in the manufacture of the cable is poured, filling up the sleeve completely, after which the holes are closed by solder. These joints have been found to give excellent service in this form of cable. The time taken in making this joint is about 30 minutes.

Lead-Covered Cable.

The cables used in the electric light service in the New York subways are, as I have elsewhere stated, without exception, lead-covered. The use of this lead covering is not required by the subway rules. In addition to being a protection against the attack of acids and gases, the lead covering is considered a safeguard against accidents to men working in the manholes among live wires. It will hardly be credited by some people, but it is a fact, that live electric light wires conveying the alternating high tension arc currents are handled and moved about in the manholes by means of the lead covering without the slightest indication that such wires are alive. In fact, it is quite a common occurrence to start up alternating circuits immediately after a rubber joint has been made, in order to save time, and then to have the plumber adjust and wipe the sleeve on to the lead cover while the current is in full operation. Another fact is this, that in the subways no shocks whatever due to induced current in the lead covering are felt by the workmen in handling the lead-covered cables conveying the alternating current. It is quite conceivable that such shocks might be noticed, as I believe they are, where the cables are suspended from point to point and insulated. It has been stated frequently that such induced currents, where the lead covering of the conductors is insulated, have been known to injure the lead covering, and eventually to destroy the insulation. So far as I have been able to ascertain, not in a single instance has such an action taken place in the subways. As a matter of fact, close personal observation and careful inquiry on all sides have failed to discover thus far any sign of deterioration in the condition of the material of the conduits, the lead covering of

Digitized by Google

the insulation, or of the insulation of the cables in the subways, with the exception of the effect upon the lead covering of the telephone cable in the creosoted wood conduit referred to. I may add that, even in the latter case, personal investigation and inquiry made of workmen have not confirmed the statement that the lead covering has been attacked. At all events, there is no evidence of any such wholesale manufacture of white lead as has been reported from other places where lead-covered cables have been placed in creosoted wood boxes.

Insulation and Tests.

The rules of the Subway Company require an initial insulation resistance of 15 megohms per mile per 100 volts electromotive force employed on the circuit, and a minimum of 5 megohms per mile per 100 volts. The initial test is made when the conductor is first laid in the subway, and prior to the turning on of the current. The minimum requirement is allowed after the circuit has been in use. This insulation requirement refers to the conductor proper in the subway, and does not include the lamps, aerial connections, or converters. The rule does not apply to conductors conveying currents of less than 100 volts E.M.F. In the case of alternating circuits, the uniform electromotive force employed in this city being 1,000 volts, the conductors to be employed in this service are required to show an initial insulation resistance of 150 megohms per mile, and a minimum insulation resistance afterwards of at least 50 megohms per mile. The average E.M.F. of the arc light circuits in the subways is about 2,000 volts, but in some instances it runs up to 3,500 volts. In the latter case the initial insulation resistance required by the rules is 525 megohms per mile; minimum, 175 megohms per mile.

It was at first thought by many that it would be impossible to maintain even the minimum insulation resistance required by the rules. One expert repeated the very common remark that one megohm, *if it could be maintained*, would be quite sufficient for practical purposes. I do not think this statement will be seriously contradicted, but the difficulty is to maintain the insulation resistance at one megohm in practice. Experience in the New York subways has shown that it is vastly easier to maintain the insulation resistance at 150, and even 500 megohms per mile, than it has been in the past in other cities to maintain them at one megohm per mile. A gentleman writing of the Chicago underground system, not quite two years ago, remarked: "It was found that although the insulation measurement of the lead-covered cables in the conduit was very high, considerably above a megohm, a short circuit would form, generally within 1,000ft. of the station, between the two sides of the circuit. The explanation for this short-circuiting under such conditions would appear to be simple, namely, that if the insulation resistance of a conductor is but one megohm per mile, the covering being of the ordinary thickness, it is clear enough that it is decidedly inferior insulation; and if the normal insulation resistance of the conductor is very much higher than one megohm per mile, but the measurement nevertheless shows it to have an insulation resistance of but one megohm, it is or should be sufficient evidence that a fault has developed in the insulation which surprises no one when it produces a short-circuit or burn-out.

As I was in no wise responsible for the subway rules, modesty need not restrain me from saying that experience of over a year has amply proven the wisdom of those requirements. For these requirements not only necessitated the use of an insulating material possessing high specific insulation, but also compelled the exercise of the greatest care in the details of placing the conductors in the conduits, in the making of joints, &c. When it is stated that these conductors are jointed at every manhole, and in many instances at several places between manholes, the need of such carefulness in order to maintain a high insulation will be understood. If, for example, the method of making joints that was employed some years ago in Philadelphia—namely, to strip the ends of the lead covering for two or three inches and then to place three or four turns of tape around the ends of the conductor—had been followed in the New York subways, I make no doubt I would have had to report to-night a continued series of failures in the electric light service similar to those so often quoted as having happened in Philadelphia. I am confirmed in this belief by the fact that the first electric light conductors laid in the New York subways were found to possess an insulation resistance of but little over 100,000 ohms—this, notwithstanding that the insulation resistance of the conductors at the factory was over 2,000 megohms per mile. There were about 40 joints in these conductors. Where these had been cut out and new ones made by an expert jointer the insulation resistance rose to over 1,500 megohms per mile, and a very recent test of the same circuit shows it to possess virtually the same insulation resistance.

The high-tension electric light conductors are tested weekly for insulation resistance. The tests are made by the direct deflection method, a Thomson reflecting galvanometer being used, and, as a rule, a 100-cell chloride of silver battery is employed as a testing battery. The tests are generally made from some room or basement adjacent to the terminals of the conductors in the subway, in order that the subway portion of the circuit may be tested exclusive of aerial portions. The subway conductors are, as a rule, tested exclusive of arc lamps, converter, and inside wiring, but frequently also the tests are made inclusive of arc lamps and converters. These latter tests are only accepted when the results fairly indicate that the fall of insulation is due to the lamps or converters. In quite a number of cases the tests with converters included show an insulation resistance up to the requirements. Tests of circuits are not made inclusive of house-wiring, because of the generally low results of trial tests. Some such tests that I have made showed an insulation resistance of the house wiring of less than 1,000 ohms.

The following record of actual tests may be of interest:—

Circuit A, Arc. Initial test, 588 megohms per mile. Last test of same circuit, 388 megohms. Present length of circuit, 9·5 miles.

Circuit B, alternating. Initial test, 141 megohms. Last test, 1,250 megohms. Length, 9·6 miles. The first test was made when circuit was much shorter than at present, and, doubtless, the terminals of conductors were exposed during that test.

Circuit D. Initial test, January 6, 1889, 224 megohms per mile. Length of circuit, 4 miles. Subsequent test, January 2, 1890, 484 megohms per mile.

Circuit E. January 4, 1889, 1,750 megohms per mile. Same circuit, January 4, 1890, 1,516 megohms per mile. Length, 1 mile.

Circuit F. July 7, 1889, 264 megohms per mile. January 3, 1890, 343 megohms. Length, 6·6 miles.

The readings for these tests are generally taken after one or two minutes' electrification.

Tests with converters included in some cases show very fair insulations. One circuit with 34 converters included showed 11 megohms total insulation resistance. Another with 11 converters included gave a total insulation resistance of 159 megohms. It is not uncommon to get an insulation resistance of from two to five megohms with 30 and 40 converters in circuit. These tests did not include aerial portions in circuits. It should be said that the insulation of the converters and connections is being constantly improved, and, in my opinion, the time is not remote when the underground circuits will test up to requirements at all times with converters included.

Contrary to the expectations of some people, the actual making of these electrical tests has not been attended with any serious difficulty. The most troublesome factor has been that due to surface leakage at the battery or other parts of the testing equipment, during the very humid weather which prevailed so continuously last summer and winter. The time for making these tests is as far as possible chosen to suit the convenience of customers. The majority of the tests are now made in the early mornings. All circuits are tested once a week at least.

About 130 miles of the subway electric light conductors referred to are employed as carriers of alternate current for incandescent lighting; about 60 miles as carriers of arc light, and incandescent continuous currents. The circuits vary in length from one mile to eleven miles; the longest arc light circuit is 10 miles in length—the longest alternating circuit is 11 miles in length. In 10 miles of alternating or arc circuit there are from 450 to 500 joints. The greatest number of converters on one subway circuit is 65. There are 14 arc light circuits and 25 alternating circuits in the subways. Quite recently an alternating arc circuit has been installed in the subways which is intended to be the pioneer of numerous such circuits. I may say that it is ultimately intended to operate at least 125 arc lamps in such circuits.

Lightning Arresters.

In the case of many of the electric light circuits that were first laid in the subways of New York city, lightning arresters were used at street lamps and at the terminals of the cable, and in a number of instances the same apparatus is still used. These "arrestors" are those known as the Acheson cable protector (*Electrician*, September 21, 1888, page 630), and are intended to protect the cable against disruptive discharges from any source. The utility of this device for the purpose intended has yet to be demonstrated in this city, inasmuch as the frequency of burn-outs in unprotected cables in the subways has been no greater than in those which are equipped with the protector, the percentage of burn-outs on cables in either case being, as I have before intimated, very low. It is as yet, I think, an open question whether the use of this or any equivalent device is warranted. There is no record of any of the cables in the New York subways having received injury from lightning during the past year.

It is commonly supposed that the freedom from burn-outs which the successful electric light cables in the New York subways have enjoyed, as compared with the earlier experience of other cities, is

Digitized by Google

due to an increased thickness of insulation around the conductor. This may be the correct explanation; but the fact is worthy of attention in connection with this subject, that certain electrical condensers have for years been placed in positions where they are exposed to the full effect of lightning discharges on telegraph lines, without in a single instance having sustained injury therefrom. Similar instruments have also been placed across the poles of 1,000 volts alternating dynamo machines for days without perceptible harmful effect. Since it is difficult to imagine a better opportunity for a disruptive discharge to effect its escape to earth than that presented by the extremely thin tissue paper used in those condensers, the thought is suggested that if this paper can be so constructed as to act as a barrier to the passage of such charges there may be more to be considered in this matter of insulation than the mere question of thickness of the insulating material.

Alleged Dangers of the Subways.

The dangers to be apprehended from the existence of the electrical subways and from the placing of the high-tension wires therein, according to those who are perhaps more or less inimical to that action, are varied. In general terms they say that the dangers which menace the public and *employés* from the presence of wires overhead will be multiplied manifold when the wires are underground. But, when asked to specify those dangers, the reply is limited to the following, namely:—first, that linemen will be killed by coming in contact with live wires in the manholes; second, that high-tension currents will leave the subways and enter buildings by way of water and gas-pipes, &c.; and, third, that accidents due to explosions of gas in the subways will be numerous.

As regards accidents to workmen in the manholes, due to contact with live wires, no one will say that such occurrences are impossible; but inasmuch as not a single accident of this kind has occurred in New York City, or, so far as I can learn, elsewhere in electrical subways, it is fair to assume that, with the exercise of proper supervision of the wires, this is not likely to prove a frequent source of accident. I have already suggested in another place that the fact of the wires being metallically covered may have conduced to the immunity from accidents which the workmen in the manholes have enjoyed. I may interpolate here that it is recognised that the efficiency of the manholes would in many instances be increased if they were larger; and, wherever the surrounding condition of the street will permit, it is, I believe, contemplated to enlarge the manholes.

So far as the statement is concerned that danger is to be apprehended by the entrance of powerful currents into buildings by way of water and gas pipes, by contact of a grounded conductor in the subways, it would scarcely be worthy of notice before a body of electricians, but for the persistency with which it is said to be urged by men of prominence in the electrical profession. It is conceivable that if a conductor, within a building, should by accident come into contact with a well-insulated gas pipe also within a building, one might receive a shock by contact with the gas pipe if in some manner he should complete the circuit; but in what manner, in the event of a ground in the subways, any dangerous current can be conveyed to the inside of a building by means of gas and water pipes which have the entire area of the city's foundation as a ground or return circuit is more difficult to understand.

Gas in the Subways.

In my opinion the presence of gas is the most serious defect of the electrical subways in cities; of course, it is not an inherent defect in the subways, but it is nevertheless a very troublesome one, not only because of the danger of explosions therefrom, but also because of its ill effects upon workmen employed in the subways. As previously remarked, the ducts used in the subways are not only joined together as nearly hermetically as possible, but, except in the case of distributing ducts, they are laid in a solid body of cement from manhole to manhole. It is supposed that the gas obtains ingress to the manholes through the place where the iron manhole cover rests upon the masonry of the manhole. But at whatever point the gas enters the subways, its unwelcome presence is acknowledged; and while it is self-evident to any one who will investigate the matter for himself, and is actually admitted by the gas companies that the gas emanates from the gas mains in the streets, nevertheless the subway engineers have been constantly at work devising means to remove the intruder. To this end various methods for ventilating the subways have been suggested and tried, the most successful of which thus far has been the ventilation of the subways by the use of blowers stationed at intervals along the subways; and arrangements are now in progress to place fifteen such blowers in operation to cover the entire subway system. As the ducts become filled with cables, however, the free passage of air through them is prevented, and in this way the utility of the blowers is diminished. In order to evade this difficulty a 6in. wrought-iron pipe has been laid above the subway ducts in the more recently constructed subways. This large iron pipe has openings at each manhole. The openings are graduated as to their extent as they recede from the source of the air pressure. The larger openings are at the points remote from the blower. It is intended by the use of these large pipes to furnish a counter-pressure in the subways somewhat exceeding any tendency of a pressure from the outside—rather than to produce a strong current of air through the ducts, and in this way to prevent the ingress of gas through any crevices that may exist in the subways.

It has been frequently suggested that good results might follow a suction method of ventilation; but experience has shown that this would rather aggravate the evil, as it would draw into the subway all the accumulated gas in the streets, besides inviting a large leakage from the gas mains. The only beneficial effect to the subways of this resort to blowers to drive out the gas is that the air dries up the ducts and manholes within quite a distance of the blowers.

The cause of these explosions in the subways has not in every case been definitely located. It is, of course, known that they are due primarily to the ignition of an accumulation of illuminating gas mixed with atmospheric air in the explosive proportions, but the difficulty has been to ascertain by what means the gas has been ignited. It is on record that these explosions have occurred in sections of the subways in which there were at the time no wires whatever. And in cases where there have been live wires in the vicinity of an explosion, tests made immediately after the event have shown that those wires were in practically perfect condition as regards insulation. There are but three instances on record in which a defect in an electric light cable has occurred simultaneously with an explosion in the subways; and in one of these cases the defect occurred so nearly incidentally with the explosion that while it is quite possible that the defect may have caused the explosion, it—the defect—may have been due to mechanical injury due to the explosion. Among other theories it has been suggested that the gas may be ignited by currents induced in the lead covering of alternating current conductors. This might be the case if, as I have before suggested, the cables were supported from beam to beam, as on a bridge, on insulated stands, and if the lead coverings only approached each other at intervals; but where the lead coverings of the conductors are not only grounded throughout their lengths, as in the subways, but are also joined metallically—in fact, are practically one cable in the ducts—it seems unlikely that a quantity of induced electricity, sufficient to produce a spark, could be accumulated at any one point. At all events, no sparks are observable in the subways at any time; and, as I have already said, there is no evidence of the generation of such charges manifested by the handling of the lead covering of the cables.

In the case of at least two explosions in New York City, the evidence showed that the gas in the subways had been ignited by a lighted lamp or match in the vicinity of some subsidiary duct connecting with the subways; in other instances by a match or lighted cigar thrown in a manhole. It is known that in Chicago an explosion was caused in the subways by a live coal from a passing fire engine falling upon the cover of a manhole. With but one or two exceptions, the explosions have not injured the cables in the subways, which is probably due to the small and round surface which the cables present.

It has frequently been suggested that if solid ducts were employed instead of tubular ducts these explosions would be avoided. While this would be, if correct, a strong argument in favour of solid conduits—that is, ducts in which the conductors are not removable, notwithstanding the generally admitted fact that such ducts are not practicable for subway work on a large scale experience has demonstrated that explosions have occurred repeatedly in manholes and in small junction-boxes of subway systems in which there were no hollow ducts. I may add that, pending the installation of blowers in certain of the subways, men are employed day and night opening manholes to permit escape of gas. I had intended to comment briefly on the comparative expense of maintenance and reliability of underground wires in cities as compared with overhead wires; but as my Paper has far exceeded the limits which I had placed upon it, I shall leave that and other features in abeyance for the present.

The following are some of the rules of the subways of New York City which have been promulgated as precautionary measures or as a result of actual experience.

No bare ends or bare portions of conductors, whether in or out of service, are permitted in the manholes. No joints, except such as are protected by a metallic covering, are permitted in the manholes. All conductors in manholes are required to be arranged symmetrically around the walls and to be plainly tagged with the designing mark of circuit and the name of the owner. No switch-boxes are allowed in the manholes.

In conclusion, I think it may be said that the experience derived from the practical operation of the electrical subways of New York City has either made apparent or confirmed, among other things, the following:—

That it is possible to successfully operate all classes of electric conductors underground in cities. That, at least for conductors conveying high-tension currents underground, it is advisable to set

Digitized by Google

the standard of insulation high. That regular insulation tests of the conductors are very valuable. That liberal thickness of insulation is desirable for high-tension currents. That it is unadvisable to place under ground new types of cable or insulation until they have been subjected to tests and conditions analogous to those to which they will be subjected underground. That for electric light conductors—especially distributing mains—many conductors under one cover are not advisable, owing chiefly to the difficulty in making joints in such cables. And lastly, that while other features may be accessories thereto, the employment of smooth, strong conduits, accessible ducts for distribution of the current, first-class insulation, constant expert attention to details, and thorough organisation in every department, are essential to the production of a successful electrical underground system.

NINE YEARS WITH THE ARC LAMP.*

BY M. D. LAW.

The subject of this Paper is one that is of interest not only to every central station man, but also to those who handle arc lights in isolated plants; and if I can give you but one point that is of value I shall feel amply repaid for my labour. There are a large number of irregularities in arc lamps that can be remedied by a judicious study of their actions; and, after the cause of their trouble has been found, it should be remedied even if the lamp has to be rebuilt.

In order to find the special trouble that arc lamps are subjected to, a careful record should be kept of each and every lamp. To do this, give each lamp its individual number; then, by the use of a numbered book, allowing a page for each lamp, a record may be kept of all lamps, where they are, when changed, with the kind and amount of repairs. This method of keeping a lamp record allows of finding the peculiar trouble that the lamp is subject to. If a lamp is continually being changed for the same cause, there is some one thing that is radically wrong, which is causing the trouble; this should be found and rectified. For instance, a lamp may work perfectly on the test rack, but after being in use for a short time, would have to be changed for dropping. If from the records of that lamp this is found to be its general complaint, then look for the trouble, if a Brush lamp, in the winding—that is, there may not be the proper resistance of wire on the magnets, or there is too great a difference in resistance between them, which should not be more than one ohm, or the result is a side-puller. The resistance of the magnets should be kept as near as possible to 85 ohms; never allow more than three ohms variation from that amount. Binding of the mechanism, large washers, or too high adjustment of the arc, will cause dropping. In hunting for the cause of this trouble in the Brush lamp, I found that, with proper construction, it could be made to work without dash-pot or spring, better than the old style with dash-pot and spring. I assumed that in a differential magnet there must be a point of equilibrium between the two magnetisms, and that, if the cores were accurately suspended at the centre of this point, any variation of current would affect the core quicker if so suspended than if it were forced to or from that point by a spring; this I have found to be the fact.

Another point wherein expense is saved in the Brush lamp is in the winding of the cut-out magnet. Divide the magnet in two parts by an extra fibre-head, and by winding the fine wire at the top, with a resistance of 15 ohms; the coarse wire can then be wound on at the bottom, allowing the end to make connection with the cut-out armature at least half an inch from the head of the magnet; this will reduce the chances of burning out. If there is a bad contact when the lamp cuts out, even if it does burn out, only one wire will have to be removed. If the following rules are strictly adhered to in the putting together of a Brush lamp, it will be found to burn correctly with but little adjusting:—

See that the upper carbon-holder is in line with the rod. This adjustment is very important, and is made by clamping a steel rod of the same size as the carbons to be used in the holder, and revolving it between the thumb and the finger, noting whether the lower end of the testing rod revolves on its own axis or "wobbles." In the latter case, push the holder up to the lamp box, and, by means of the testing rod, bend it slightly in the proper direction to correct the error, then see that the carbon-holder has not become loosened; test again, repeating the process until the desired adjustment is reached.

Examine the lifting washers which surround the carbon rod; see that the hole is counter-sunk on each side, so as to make the available thickness of the washer where it touches the rod but little more than one-sixteenth of an inch. See that the hole in the washer is of such a size that one side of the washer may be raised one-sixteenth of an inch from the horizontal floor on which it rests, before it clamps and commences to lift the rod. See that the holes in the washer and bushings are nicely polished. The lifting finger, designed to lift the washer, should move freely in its guide and get a good hold under the edge of the washer, and allow the latter to rest flat on the floor under it when the finger is down. In the case of double lamps, the lifting finger should be so adjusted as to lift the second rod one-sixteenth of an inch ahead of the first.

See that the movable brass parts connecting the lifting finger with the movable magnet cores work freely at their joints, so that no binding of the parts may be possible. The spring which partly supports the magnet cores should be made of steel "pianoforte wire," twenty-seven thousandths of an inch in diameter, wound closely over a mandrel of such size that the spring when released shall have an external diameter of seven-sixteenths of an inch, and shall consist of about 38 turns of wire exclusive of the hooks at the ends. See that all the parts of the dash-pot are free and do not bind. See that the armature of the cut-out moves freely on its pivot, and when it is down its end is about one-quarter of an inch from the core of the cut-out magnet; and when it is raised and makes contact with the copper wire projecting from the cut-out magnet, that its end comes about three thirty-seconds of an inch from the cut-out magnet core. The brass spiral leading from the cut-out armature is not used as a spring, but as a resistance. It must be pulled out or pushed together as the case may require, that it shall exert neither a lifting nor depressing influence on the armature. This spiral is made of brass wire twenty nine-thousandths of an inch in diameter and about 30in. long before being coiled. The size of this wire is important, as it should be of just right resistance, that the lamps may cut in when the carbons come together; for this same reason the armature is not allowed to come close to the core of the magnet, but should be made to come as close as possible that a better contact may be made, thus reducing the liability of burning out.

The principal improvements that can be made in the Thomson-Houston lamp are the making of the clutch of German silver or some more durable metal than brass, as the bearing point of the clutch against the rod is so small that it very soon wears, and thus throws the lamp out of adjustment. When one of these lamps is found dropping, it can very often be remedied by lowering the adjusting nut No. 692 a trifle, when the lamp will again burn correctly, and, in some cases, this may be repeated several times without any other change in the lamp.

Another great point of improvement in this lamp is increasing the thickness of the insulations, which are too small in nearly every case; especially is this the case with those under the binding hooks at the top of the lamp box, which I find work excellently well when made of porcelain. When the insulator in part No. 701 gives out, the current shunts through the cut-out magnet, causing what the men term "cut-out armature magnetised." This is a very important point, which produces flaming and dropping.

The general causes of the Thomson-Houston lamps dropping are numerous; but if all the working points move freely and without lost motion, it will reduce the number to the few following points:—Badly-worn spots in the carbon rods; the clutch or lifting springs may have lost their temper (these should be made of bright instead of black steel); bent clutch arm; worn clutch or carbon rod bushings. The adjustment nut No. 692 may be too high; the clutch or tension spring may be too tight. Crooked frames, bent rod or rods striking the chimney, tight bushings, fine wire broken, dirty rods, or the adjustment nut No. 692 being too low; brush in the bushing may be too tight or become corroded or burned, and the magnetising of the armature before spoken of will cause the lamp to flame and drop.

The globe-holder or carbon-holder of the arc lamp is a very much neglected part—that is, the insulations are not made heavy enough, and the carbon dust or copper droppings falling over the insulations will give sufficient leak for a person standing on the ground and touching the bottom of the lamp to receive a very bad shock; this insulation should be made heavy and so placed that the carbon dust may not fall on it, as it is sometimes impossible to hang lamps under awnings high enough but that, when a person passes under them, they may be touched by any conductor which they may have in their hands. No part of the lamp outside of the globe should be allowed to have current in it. Arc lamps should be suspended by some perfect insulator, the regulator porcelain insulator and hook being the best in our experience. Never allow crocus or emery to be used, as it badly wears the rods in the centre. A better plan is, if the rods become rough or dirty, bring the lamp in and polish on the buffing-wheel, which will allow of its being kept of an even size its entire length.

The longest record for any one lamp in a constant street service is three years and nine months, without any adjustment other than the ordinary cleaning by the trimmer.

The most vexatious part of the arc lamp is the globe; it swells the item of expense in spite of the utmost care, besides being a

* Read before the National Electric Light Association, at Kansas City, February, 1890.

Digitized by Google

great source of complaint; for I never knew one to be well enough cleaned but there would be a complaint that it was not polished. Undue heat after the carbon has burned close to the holder is one of the greatest causes for broken globes. This can be partially overcome by leaving the globe about one and a-half inches from the carbon-holder.

The waste in the use of carbons is a very important feature. These should be dealt out, and every stump returned; the amount saved in laying by the four and five-inch stumps, to be used in the summer months, will make a saving of at least ten thousand carbons per year for a one-thousand light station. At the time I first started dealing out carbons and bringing in stumps, I saved on an average over thirty dollars per month, and then only trimming about four hundred lamps per day.

While I am a great believer in the use of the best quality of insulation for line construction, yet it is not best to depend entirely on such insulation for safety. Put up the best wire there is, and then apply a rigid system of inspection and tests, not by that abomination of tests, the magneto bell. Not only should the tests be made on dead lines, but should be made at least once in two hours on all live wires, and when grounds or bad leaks are discovered they should be immediately cleared, by that means preventing the second ground, which is the element of danger. I have repeatedly had lines that would test clear at the time of putting on circuits; but two hours after solid grounds have been discovered, located, and found to be wires broken down, hanging over the electric light wires and reaching down to the sidewalk, where they are a source of danger to every passer by. All lines should be cut by one man, who is especially instructed and detailed for that work, as then you are enabled to pick out a thoroughly reliable man and drill him in the work that he is to do; then, by never allowing a circuit to be opened, and teaching all men to never depend on any insulation, but to treat all wires and lamps as if they were charged with an electric light current, danger to *employés* will be reduced to a minimum.

Supplementing the Paper, Mr. Law said:—Another point to which I would like to call your special attention is in the matter of testing arc light lines. It has only been within the last six or eight months that we have been putting a thorough test to line wires. I can now positively locate a ground at the station before leaving to hunt it up. These tests are made at regular intervals of about two hours during the night and day on all live circuits. As soon as those grounds are discovered my foreman is notified and I also receive notice myself, and the proper men are detailed to remove them as soon as possible.

The manner in which I have been testing grounds at our station for the past year or eighteen months is by the use of a set of incandescent lamps in series; that is, I use 47-volt lamps for a 60-light machine; these lamps are put up out of the way and a wire run from each one of these lamps to the switch plate. There is a lever arranged to turn around in a circle, making a short circuit of one, two, three, four, five, &c., to cut out one or all of these lamps. Now, if a wire drops down on an electric wire grounding it, the distance which that wire is away from the station is simply a measure of potentials. Every two hours we test each one of our circuits in the first place by testing across the circuit. The number of incandescent lamps then burning up to 48 volts indicates the number of lamps that are actually burning on the circuit, less the resistance of line, which I find amounts to about ten miles of number 4 wire for every arc lamp; then we test by placing one side of the incandescent circuit to ground and the other side to line; then by turning off my incandescent lights until I bring the voltage up to 47, I find a certain number of lamps burning. We will say ten lamps on the positive side; now I turn my attention to the negative side and go through the same operation. If I find that I have fifty lamps on the negative side, I know that the ground is ten arc lamps away from the station on the positive side, and if your circuit books and diagram books are correctly kept, you can tell in two or three moments' time exactly the location of that lamp. In 99 times out of 100 we go to the right lamp.

THE HEYMANN DYNAMO REGULATOR.*

In a patent recently issued to Edward and Frank W. Heymann, of Boston, the inventors describe a method of dynamo regulation which is based upon controlling the electromotive force in the armature coils by means of a shunt circuit so arranged as to act by induction upon the armature coils, a variable resistance in that shunt circuit being adjusted from time to time to regulate the differences of potential between the terminals of the work circuit.

As shown in the accompanying illustrations, the regulation coils C C′ are in the shunt circuit, *b* C C′ *b*′. When at full load, the resistance R is so large that the shunt circuit *b* C C′ R *b*′ (Fig. 1) is practically open, and there is little or no current in that shunt circuit. If one of the lamps, L, be switched out, the current in the work circuit B L F F B′ will tend to increase. But if the resistance R in the shunt circuit be reduced, the current in the work circuit will be thereby kept constant, for the reason that the

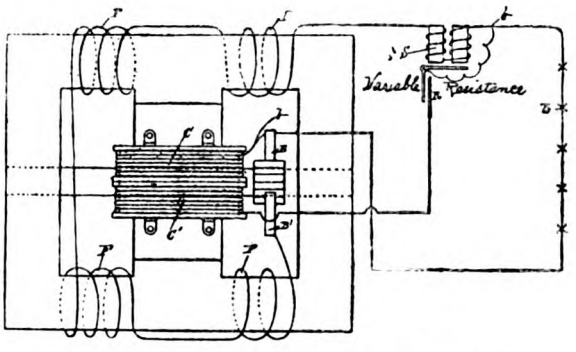

Fig. 1.—The Heymann Method of Dynamo Regulation.

current through coils C C′ will so reduce the electromotive force of the armature coils as to make the difference of potential between the brushes B B′ suitable for giving the desired current in the work circuit. Consequently, if the resistance R be reduced whenever the resistance in the work circuit is reduced, and in the proper proportion, the current in the work circuit B L F F B′ can be maintained constant, and this with proper economy for practical purposes.

In the case already described the difference of potential between the brushes B B′ or between the junctions *b b* requires to be varied in order to keep the current constant, in spite of variations in the

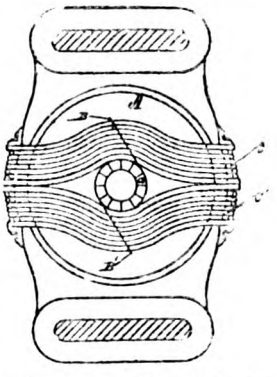

Fig. 2.—The Heymann Method of Dynamo Regulation.

resistance of the load. In case of a constant-potential machine, however, the object is to keep the difference of potential between the brushes B B′ constant, whatever the resistance of the load, and consequently the current may vary. In this case, under full load, the resistance R in the shunt circuit *b* C C′ R *b*′ is at the maximum, as before; but when one lamp is cut out the resistance of the load is thereby increased, and the tendency is in that case to increase the difference of potential between the brushes B B′; but that difference of potential can be maintained constant by decreasing the resistance R as the resistance of the load is increased.

It will be seen that the shunt circuit *b* C C′ R *b* is not a mere shunt—that is, as if the regulating coils C C′ were not present—for if the coils C C′ were absent the current through *b* R *b*′ would be considerably more than it ever would be through *b* C C′ R *b*′. That is to say, the coils C C′ regulate the electromotive force of the coils of the armature and also set up a counter electromotive force, which not only lessens the current through *b* C′ C R *b*′, but also regulates the difference of potential between the brushes B B′.

THE CITY OF LONDON AND SOUTHWARK SUBWAY RAILWAY.

This Bill, which asks for powers to extend the above railway to the "Plough," Clapham, came on for hearing on Tuesday before a Committee of the House of Commons, consisting of Mr. Walter James (Chairman), Mr. Esslemont, Sir Richard Temple, and Sir Edward Grey.

Mr. J. H. GREATHEAD, engineer to the line, in examination by Mr. RIGG for the promoters, said:—With the electric locomotives they now had they could run at a speed of 25 miles an hour between the stations, and they could get an average speed from spot to spot of 20 miles an hour, and probably, including stoppages, of 15 miles per hour. They had made successful trial trips on part of the line between the City and Great Dover-street and the Elephant and Castle, with electrical locomotives and carriages weighted to the full load of three carriages.

Dr. JOHN HOPKINSON felt certain that the proposal to work the City and Southwark line by electricity would be attended with perfect success. The dead weight to be driven for every passenger being two-thirds less on the Subway than on the Metropolitan Railway, and also the load on the generating machinery being much more uniform in the Subway, he had no doubt whatever that the amount of coal burnt for every passenger carried when the trains were fully loaded would be much less in the Subway than on the Metropolitan Railway. There would be no disturbance to telegraphs or telephones. The railway was entirely enclosed in a tube of iron which would conduct away any leakage currents. The actual power used would amount at times to over 100 horse-power on each locomotive. At Newry there was only one dynamo machine upon the motor car, but in this case there would be two, generating 50 horse-power each. The gross weight of a train in the Subway would be 29 tons loaded and 22 tons unloaded, and the maximum speed 25 miles an hour. The tractive force of the locomotive would be about 3,000lbs. at its maximum.

Cross-examined by Mr. POPE: No doubt the current would be generated more economically at Stockwell for the whole of the line than for part only—that is to say, that which was generated at Stockwell would be applied to the extension. The generating station would be more nearly approximating to the centre of the line.

Cross-examined by Mr. ERSKINE POLLOCK: The tension of the current passing along the conductor would be about 500 volts. It would not be dangerous to life.

The further consideration of the Bill was then adjourned.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—FRIDAY, MARCH 15TH.

The DUKE of MARLBOROUGH rose to ask Her Majesty's Government what steps it was intended to take this Session with regard to appointing a House of Lords Committee to carry on further the investigations of the House of Commons Committee of 1885 on the subject of telephone wires and communications; and to inquire whether Her Majesty's Government had any intention, on the expiry of the English telephone patents, to take up, under the direction of the Post Office, the extension of the telephone system in this metropolis and between large towns, and provide those advantages to the public and to private customers at a cheap rate; also whether, in the case that the proper organisation of such a system should appear to the Post Office authorities to be too large an undertaking, entailing a large initial expenditure and considerable organisation, whether Her Majesty's Government intended to give better facilities than had been heretofore obtainable to any public company or companies for carrying out this much-needed requirement. The questions really had reference to the motion which he had brought forward last year when he asked what the intentions of the Government were with regard to the telephones of the country. He thought the feeling was pretty general that the telephone was one of those valuable inventions as to which they ought to have an inquiry. In order to develope the telephone system in London a very large expenditure of capital would be required. No company, he thought, ought to start short of a million of capital. It therefore became a question whether Her Majesty's Government would recommend an expenditure of so large an amount to establish an organisation quite as important as the Post Office. This was a question for the Government to consider. The Postmaster-General had the power of running wires where he pleased as long as no damage could be proved to result, and without that power it would be impossible to have a system of telephones for London. If the Government were to depute the telephone system to public companies, had they the right to concede the power of running wires, and were they prepared to concede that power? Again, if there were to be public companies was there to be public competition? If there were, the competition would have to be limited to two companies at the most. Otherwise the benefits of the system would be greatly depreciated by persons wishing to communicate with each other being attached to different companies. Moreover, to have many companies would lead to indiscriminate wire running, with results as confusing as had been experienced in New York. Again, if the telephone system were deputed to public companies there was no doubt that the telegraph would be largely superseded. It would not be right for the Government to burke a great invention merely because it interfered with the telegraph system which they had taken over; but it was in the power of the Government, without doing this, to protect themselves. The telephone system was worked at a great profit, and therefore the Government would be justified in charging very high royalties and in conceding the powers which the Postmaster-General possessed, while they might keep in their own hands the main trunk lines between great towns. This would prevent the telegraph receipts from falling off unduly. The telephone would undoubtedly interfere with municipal telegraph receipts, but protection could be found in the royalties. He therefore asked whether Her Majesty's Government thought it would be advisable to have a Committee to inquire into the question of overhead wiring, and whether the Post Office should adopt the working of this great system of telephones; whether Her Majesty's Government would be prepared, if they decided not to take up the question, to grant to public companies the right which the Postmaster-General now possessed; and whether they would refrain from granting those rights to more than two companies.

Lord BALFOUR said that all would agree in the great importance of the subject now brought forward, and all would be equally unanimous in the desire that no undue obstacles should be in any way opposed to the development of the telephone system for the convenience of the public. The questions of a kindred nature which the noble duke brought forward last Session were somewhat different from those now raised, involving as they did questions of electric lighting overhead wires, as well as a considerable scheme for amalgamation. The noble marquis at the head of the Government then said that he did not think it was a desirable subject for inquiry by the House, and now he had to repeat that view of the matter, but with a stronger reason. Some patents of great importance would expire at the conclusion of the present year, and he was authorised to say that the relations of the Post Office with the telephone companies were at present under the consideration of the Government. This involved large questions of private right, and therefore it was not very desirable that at this stage of affairs the matter should form the subject of investigation by a Committee. The more usual and proper course would be for the Government first to make up their minds as to what proposals should be placed before Parliament, and that Parliament should express its opinion on those proposals when submitted. Therefore he hoped that the noble duke would not press for an inquiry by a Committee of their lordships' House. With regard to the first clause of the motion, there was not, of course, absolutely the same objection to the inquiry. But in the circumstances of the case, and remembering that the matter was inquired into by the House of Commons in 1885, he would express the general opinion that it was undesirable to reopen the question at the present time. He was far from saying, however, that the whole question was thoroughly threshed out by the Committee of the other House, and undoubtedly considerable confusion existed as to the exact state of the law. If the noble duke pressed for a committee of inquiry, and would put the exact terms of the motion of reference on the paper, the Government could promise to give it the most careful consideration.

The DUKE of MARLBOROUGH said that as to the difference between the present motion and the motion of last year, he wished to avoid any question of electric lighting wires, as they were a proper subject for the Board of Trade to deal with. Undoubtedly, until Her Majesty's Government had expressed their intention with regard to the present companies it would be inadvisable to inquire into the development of the telephone system. But with regard to the running of overhead wires, he thought that the report of the House of Commons supplied complete information. He would press upon the Government the great desirability of intimating as soon as possible the line of conduct which they meant to adopt, and they should also state whether they meant to give powers to public companies, and, if so, under what conditions. He would, therefore, withdraw the motion which stood in his name.

CORRESPONDENCE.

ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Reckenzaun, in his criticism on my letter, seems to have lost sight of the fact that I was dealing with a particular case, viz., that of the Barking-road line. This will explain my having included drivers' wages in my estimate, as this item was there included in the expenses undertaken by the Traction Company, though I am aware this is somewhat unusual. As to the figure I gave for these wages, ·6d. per car mile, as I explained, I put everything down at the lowest possible figure. At the same time I may point out that I gave the Traction Company the benefit of supposing that they were capable of something better than 70 miles per car per day (decidedly a low mileage for a mechanically driven car); and that, on the other hand, we should probably never have heard so much of "slavery" on the tramways if drivers were usually paid at the rate of 6s. a day, as Mr. Reckenzaun thinks they are.

The difference between the two estimates for the cost of steam power is also to a great extent to be explained by a similar consideration. Mr. Reckenzaun takes as his basis an engine of 200 horse-power. On the Barking-road, where five

Digitized by Google

cars at the most are running, an engine of one-third of this capacity would be sufficient, and of course the cost of power would be considerably higher.

But, after all, the principal point on which we are at issue is as to the cost of renewal of accumulators. I put this at 1½d. per car mile as a minimum; and Mr. Reckenzaun asserts that 1d. will leave a handsome profit, "a most desirable business for anyone who understands it, whose works are not hampered with a huge capital, plus debentures, and whose administration and office expenses can be kept considerably below £10,000 per annum." But why should a profitable business not be desirable for anyone with a large capital and heavy expenses? Surely it would be all the more desirable, and, if so, why is it not undertaken? There would be an ample field for it, as it would greatly simplify the introduction of electric traction, and I do not think that the Electric Traction Company would at the present time be above considering an offer for the renewal of accumulators based on Mr. Reckenzaun's estimate.

The fact remains, that in spite of numerous attempts, in no single case has traction by accumulators on a practical scale for any length of time in England, America, or on the Continent, been found sufficiently profitable to warrant its continuation; and until something like 1d. per car mile for renewals gets beyond the paper stage, I do not see how any system using accumulators can become a commercial success.—Yours, &c.,

Wimbledon, March 18, 1890. H. J. S. HEATHER.

THE "FEEDER" PATENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The interesting action about to be entered into by the Edison Swan Company to substantiate their supposed possession of the master patent on the feeder system, should awaken those interested in electricity supply into activity in opposition to the attempt to gain a monopoly that would be even more seriously influencing than that of the Glow lamp. The feeder can be applied with advantage in almost every system of distribution, whether by low or high pressure, alternate or continuous currents, double or triple wiring; and a monopoly to a form of the controlling patent on such an invention would be of incalculable value, and worth great labour to obtain. Equally disadvantageous would such a monopoly be to the trade; and this should inspire every effort to be exerted to prevent it.

The validity of the patent is one of the main points that the electrical interest can attack; and by way of a starting point I would draw attention to Werdermann's patent, No. 2,477, June 21st, 1878. Edison, it is true, worked very early in this object; but Werdermann's efforts were in advance by about two years; and although he attacks the subject slightly differently, he arrives at nearly the same result. Werdermann's method is shown in its simplest form in Fig. 1, to which he

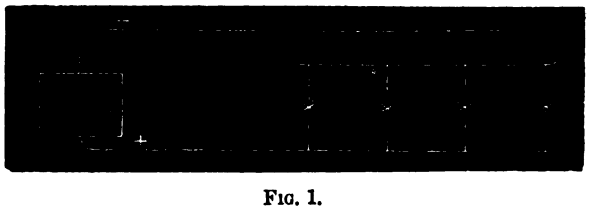

FIG. 1.

refers in these words: "I may so arrange the parallel circuits in which the lights are included that the light which is the first one, or the nearest to the source of the electricity on the positive conductor, is also the first or nearest to the source of electricity on the negative conductor. But I prefer the arrangement illustrated in the drawings in which the lamp or light which is first with regard to its position on the positive conductor, is the last with regard to its connection with the negative conductor. With this arrangement the electric current in all of the lamps or lights will have to flow through the same distance."

Werdermann shows other diagrams which are compounds of the simple one; but they are interesting as showing the method of branching on the same principle. This invention is only made a secondary consideration in Werdermann's patent; in fact, he does not refer to it in the provisional specification, consequently the description is very meagre and the main features are not pointed out, except in the diagrams. Reverting to Fig. 1, is not the lead clearly a feeder to the system of supply mains? And if we show the diagram as in Fig. 2, we have substantially Edison's feeder system with the feeders taken into the supply mains at points wide apart.

Werdermann makes no mention of these feeders directly, but they are conspicuous in his diagrams, and his system could hardly be worked without them.

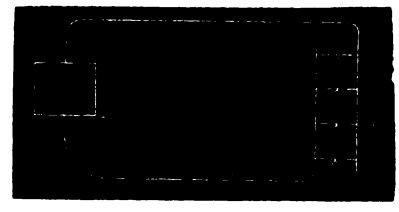

FIG. 2.

It is hard to know where the range of Edison's patent would end. A town with the supply outside would be fed by feeders, and this arrangement might have been specially made for the purpose of equalising the pressure, and could be made with advantage in some cases.—Yours, &c.,

J. D. F. ANDREWS.

Botolph House, 10, Eastcheap, London, E.C.,
March 18, 1890.

COMPOUND CONDUCTORS FOR DYNAMO ARMATURES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 14th, under the head of "Paris Notes," I notice "some interesting particulars" of a dynamo made by MM. Reignier and Bary. I beg to enclose a copy of my specification of Patent No. 126, 1889, from which you will see that the use of compound conductors is not new. Owing to a delay in the building of my trial motor I am not yet in a position to give full particulars of the working of these machines. The result, 40 watts per kilo, as a maximum output, does not do these machines full justice. In a large ring armature with small depth of core, such as that used by Messrs. Paterson and Cooper in their "Phœnix" dynamo, a result of at least 80 watts per kilo can be obtained.

In conjunction with Mr. E. Hungerbükler, I have been able to simplify these *electro-magnetic* conductors to such an extent that they can be used on the smallest machines, and even on instruments. The total cost of manufacture will not be much over that of the ordinary covered copper wire now used.—Yours, &c.,

G. B. LÜCKHOFF.

Croydon.

SUBDIVIDED CONDUCTORS FOR ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the interpretation of the patent, No. 783, taken out by Prof. Perry and myself in 1881 (as well as of numerous other patents regarding electric traction in which we are interested), must rest with a tribunal having greater authority than can be exercised by the readers of a technical journal who may glance at its correspondence columns, I do not intend to be drawn into a newspaper controversy.

I may, however, mention that when the late Prof. Fleeming Jenkin took out his patent, No. 1,830, in 1882, for a system of subdivided conductors for electric traction, in which the length of each section of the rubbed conductor, and the distance apart of the contact boxes at its ends, were *slightly less* than the length of the moving train, his own patent agent expressed the opinion that such a plan could not be worked without the payment of a royalty to Prof. Perry and myself. Prof. Jenkin

Digitized by Google

then entered into a working arrangement, by which he transferred to us two-thirds of this and of all his subsequent patents connected with electric traction taken out in Great Britain and other countries, and which numbered some fifteen, before his untimely death, in return for one-third of our patents on the same subject transferred to him.—Yours, &c.,

March 18, 1890. W. E. AYRTON.

TESTING GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We are sorry to trouble you again on this subject, but trust you will kindly give us space to reply to Prof. Ayrton's letter which appears in your issue of 7th inst.

As to the "taste" in which our former letter was written, we are content to leave the point to the decision of those more competent than Prof. Ayrton to judge of such matters; and will only say that we deferred sending the letter to you until the last possible moment, and after waiting several days for a reply to the letter we had written to Prof. Ayrton.

After we sent our letter to you, we received a letter from Prof. Ayrton, under date February 20th, as follows:—

GENTLEMEN,—I have been so busy that I have not had time previously to reply to your letter of 15th inst.

With reference to the words you quote from *The Electrician* report of the remarks I made on 7th inst. at the Physical Society, I should not, if I had been writing this report, have used the words, "as he believed this was Messrs. Elliott's usual practice," because there is an ambiguity as to whether the word "was" is used in the past tense simply from the report having been put in the third person, in which case "was" might mean that I said, "I believe this is Messrs. Elliott's usual practice." If, however, the reporter meant by the word "was" that such was your practice in former times, then the report would be correct, although ambiguous.

You are under a misapprehension yourselves in your statement to Mr. Mather that, "For the last 25 years at least, it has not been customary to use any other cell than the Daniell's in testing for the figure of merit," seeing that on my going to your testing-room in St. Martin's-lane, in December, 1868—that is, about 21 years ago—to see a galvanometer that had been constructed for me tested, I expressed my surprise to Mr. Becker that he had set up a Grove's cell to be used in testing; and he replied that he always used a Grove's cell for that purpose.

Of this I am absolutely certain, as the incident is very strongly impressed on my mind. It is, therefore, quite certain that 21 years ago the employment of a Grove's cell was your regular practice. I was very careful to explain at the Physical Society that the doubt about what kind of cell was employed only applied to that one instrument, of which both the maker and the tester were, I understood from your letter to Mr. Mather, both dead.

Please bear in mind that the report in *The Electrician* is not the official report of the proceedings of the Physical Society. This, in abstract, you will see in the *Electrical Review* and other papers of the 14th inst., and in greater detail in the copies of the *Proceedings* issued from time to time by the Society itself.—Yours, &c.,

(Signed) W. E. AYRTON.

I take this opportunity of thanking you for all the information you have been so kind as to furnish us with.

To this letter we replied, under date February 21st, as follows:—

SIR,—We are favoured by your letter of yesterday's date, which arrived after we had sent a letter to *The Electrician*, which appears in to-day's issue.

We are under no misapprehension as to our statement to Mr. Mather, and we think you will admit that we are more likely than you to know what our customs are, or have been.

As to the alleged conversation with our late Mr. Becker, we are, of course, unable to speak on the subject, as we presume no third person was present; but if he stated that it was our usual practice to use a Grove's cell in testing galvanometer values, he stated that which was untrue, and this we strongly doubt. The facts and proofs which we have would bear out our opinion that the conversation only exists in imagination.

We cannot follow your argument that, because the incident is strongly impressed upon your mind, it is quite certain that 21 years ago the employment of a Grove's cell was our regular practice.

You say that you were careful to explain that the doubt only related to one instrument, because you understood that both the maker and tester were dead; we cannot see what difference that should make, there is no question as to the cell used in testing for the value of this galvanometer—it was a Daniell.—Yours, &c.,

(Signed) ELLIOTT BROTHERS.

To this letter we would now add the following remarks:—

1. The electrician who coiled and tested all galvanometers from 1865 up to the time of Mr. Becker's death (as our books can show) is still with us, and can state positively that during this period no other cell than a Daniell's was used by him: he can further state that he never remembers Mr. Becker taking a value, and has good reason to doubt that he ever did so.

2. The galvanometer to which reference is made was ordered on December 10, 1868. Prof. Ayrton fixes the date of the test as about December 22, 1868. During this interval only four galvanometers were coiled and tested, each one of which, as shown by our books, was done by the electrician above referred to.

3. Our galvanometer testing-room was on the second floor at our former premises, and if Mr. Becker wanted to see the value of any galvanometer taken he invariably went to this room for the purpose.

For the moment, disregarding the above facts, and assuming that Prof. Ayrton did see a galvanometer tested with a Grove's cell 21 years ago, assuming even that Mr. Becker said he always used a Grove's, we would ask—

1. Was it "unquestionable taste" on the part of Prof. Ayrton, in face of the positive denial given in our letter to Mr. Mather, to make the statement at the Physical Society to which he admits?

2. What ground had he for throwing a doubt upon the method of testing a galvanometer which we had told him was made and tested several years afterwards?

3. Why should he throw the doubt upon one particular galvanometer, the maker and tester of which he understood were both dead?

We leave your readers to draw their own conclusions, as we have done.—Yours, &c. ELLIOTT BROTHERS.

101 and 102, St. Martin's-lane, London, March 12, 1890.

ENGINEERS', ELECTRICIANS', BUILDERS', AND IRONMONGERS' EXHIBITION.

This Exhibition, which will remain open for a fortnight, was opened on Monday last at the Agricultural Hall, London, N., and was then in the usual backward state. Later in the week, however, many of the exhibits were in their places, and there is every reason to suppose that, taken altogether, the Exhibition will be a success. A number of well-known engineering firms are represented, some of them with very excellent exhibits; this is particularly the case with fittings for gas and electric light, gas engines, &c.

The exhibits of Messrs. O. Berend and Co., of Fore-street, E.C., at Stand 8, were not complete at the time of our visit; but we may mention that their capital show includes a number of Hartmann and Braun's volt- and am-meters, Cathcart and Peto's portable electric lamps, Poole and White's switches and cut-outs, &c., &c.

At Stand 23, Mr. A. G. Hamilton, of York-road, Lambeth, S.E., has on view a number of very artistic electric light fittings in wrought-iron work, a branch of electrical industry to which he pays special attention.

At Stand 44, Messrs. Dan Rylands (Limited), of Barnsley, exhibit a number of samples of their glass-lined metal piping, which they claim is especially suitable for electric light mains. We believe that Messrs. Rylands anticipate a very large business in this direction. The piping consists internally of a distinct solid glass tube, which is covered and protected externally by ordinary iron tubing, a suitable cement being inserted between each, which makes the whole homogeneous and renders the pipe unbreakable with ordinary use. Messrs. Rylands claim that the pipes can be easily laid, and are cheap. No solder is required, as each pipe carries a union end by means of which the lengths are screwed up without difficulty, a thin washer of gutta-percha or other suitable packing being interposed to secure a perfectly solid joint. It is further claimed that these pipes will successfully resist the action of frost or extreme alternations of heat and cold. For electric light purposes the solid glass tube forms a good insulating medium, while the outside iron piping is a protection both to the wires and the inside glass tube.

At Stand 47, Messrs. Ramsay and Hickman, of St. John's square, E.C., have a good display of engineers' tools and surface plates, lathes, &c.; at Stand 56, Messrs. Smith and Claydon, High street, Borough, S.E., show their "Economic" durable enamel paint, which they claim is especially suitable for machinery; and

Digitized by Google

at Stand 58, Mr. Samuel Buckley, of Guide Bridge, near Manchester, has a good exhibit of engineers' tools, including tube wrenches, tube cutters, screw stocks and guides, tube vices, pipe-drilling apparatus, &c.

In the centre of the Hall, at Stand 73, Messrs. Aspinall, Aspinall, and Co. have an elegant display, showing the application of their well-known enamels to all descriptions of work. This is undoubtedly one of the neatest shows in the Exhibition.

At Stand 112 will be found a ½-horse power Fawcett gas engine. It is manufactured by Messrs. Fawcett, Preston and Co., of Liverpool. A number of advantages are claimed for the engine over others in the market, particulars of which have been promised us. We understand that an 8 horse-power engine of this type is used in the installation of the electric light at the Liverpool University. These engines are built up to 20 horse-power nominal.

Messrs. Winnall, Callow, and Winnall, of Stepney, show at Stands 123 and 172 some electrical appliances, including a new electric bell. One of their principal exhibits, however, is the Chiswick Floor-Lifter, which the Company inform us is in use by a number of electrical firms. It is designed for the purpose of obviating the difficulties experienced by persons putting machinery into floor-boarded buildings. This patent floor-lifter is an upright steel screw, for which it is necessary to make a 1-inch centre-bit hole. When that is done the floor-lifter is inserted, and by the use of an ordinary tommy the floor lengths are lifted bodily, without injury to the boards or to the ceiling underneath. This firm also exhibit a Newall engine which is to drive a Phœnix dynamo, but this was not in action at the time of our visit.

The Campbell gas engine is on view at Stand 144; and a handsome display of fittings is shown at Stand 148 by the Thomas Lighting Company.

One of the best exhibits is that of Messrs. Crossley Bros. (Limited), who have on view a 14 horse-power Otto gas engine, fitted with all the most recent improvements, and capable of indicating up to 33 horse-power. This engine is driving a 30-arc-light Thomson-Houston dynamo for the installation of the electric light put down by Messrs. Laing, Wharton, and Down, which is the largest, as it is undoubtedly the best, installation in the building. In addition to this engine, Messrs. Crossley exhibit a 4 horse-power and a 2 horse-power engine of their horizontal type, and a 1½ horse-power vertical engine and hoist.

At Stand 156, Messrs. J. E. H. Andrew and Co. show several examples of the Stockport gas engine, including one of 8 horse-power, which drives a Phœnix dynamo supplying seven Phœnix arc lamps. At the time of our visit, this, with Messrs. Laing, Wharton, and Down's exhibit, was the only installation of any magnitude in the building.

The Weymersch Electric Battery Syndicate have a neat show at Stand 169. A number of batteries of the Weymersch type are on view, together with a good display of electric light fittings made by the Planet Electrical Engineering Company (Limited). There is also exhibited a small Crocker-Wheeler 10-volt motor, used for working a model ventilator.

At Stand 173, the Blackman Air Propellor Company, of Fore-street, E.C., have an effective exhibit, the ventilators being driven by one of Mr. E. S. Hindley's vertical engines from the adjoining Stand (174), where Messrs. Hindley have on view a number of engines of their well-known types.

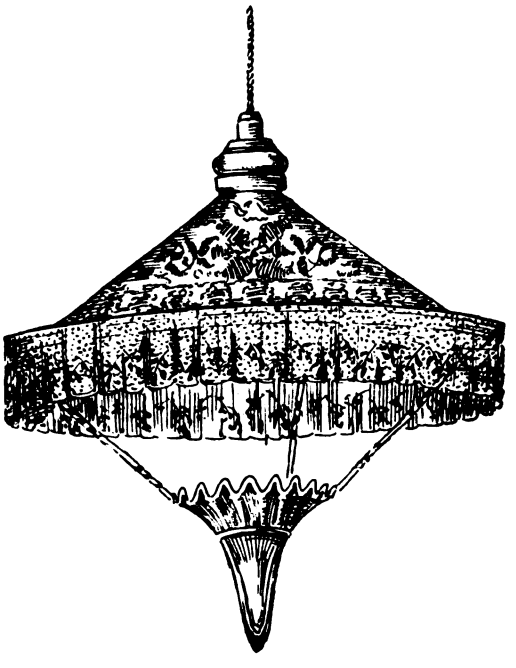
At Stand 175, Messrs. Dick, Kerr, and Co. show the Griffin gas engine, one of which is driving a Phœnix dynamo feeding a Kent arc lamp. There are also on the stand an Excelsior dynamo made by Messrs. Oppermann, and a number of instruments, switches, &c., manufactured by the Acme Electric Works. This firm hope shortly to have a large gas engine down to drive a Tyne dynamo (manufactured by Messrs. Ernest Scott and Co., of Newcastle), which is already in the building awaiting the arrival of the engine.

The largest exhibit is undoubtedly that of Messrs. Allday and Onions, who have a very effective display of engineers' tools, portable forges, stocks, taps, dies, hammers, &c.

From the above remarks it will be seen that, although the Exhibition is not a large one, there is a fair sprinkling of well-known electrical and engineering firms represented. As many of the exhibits were in anything but a forward state, we must reserve our remarks thereon until next week.

THE E. P. COMBINATION FITTING.

Manufacturers of electrical fittings are now continually introducing novel designs, and the annexed cut illustrates what is certainly a new combination for pendants, though the same idea has been for some time employed in the case of brackets. The fitting shown has been brought out by the proprietors of the "Electrical Plant" Stores, the special name of "E. P. Combination Fitting" being given to it. An ordinary opal or flint glass conical shade (etched or decorated in a variety of designs) is provided with a slightly turned-up rim, from which are hung three brass arms fixed to a brass ring underneath to carry a small glass flower or bouquet-holder. The brass arms are also provided at the top each with another hook pointing outwards (not shown in the sketch); on these hooks is placed a plain wire ring threaded through lace or silk fringe. This fitting—which is also constructed in wrought-iron, copper, or any other material lending itself to artistic treatment—presents a neat appearance, and can be turned out at a moderate



cost. It should prove serviceable for suspending over dining tables, or for use in drawing rooms and boudoirs. The makers have registered the various designs and patented the combination as applied to a pendant.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Sale by Auction.—The sale by auction of the modern engineering machines, tools, plant, and stores will take place at 417, Old Ford-road, Bow, London, E., on Tuesday next, at 12 noon prompt. Further particulars will be found in our advertisement columns, and catalogues can be obtained on application to Messrs. Wheatley Kirk, Price, and Goulty, 52, Queen Victoria-street, London, E.C.

Messrs. Johnson and Phillips.—We have received from this firm Catalogue and Price List No. 3, containing illustrated descriptions of the well-known Brockie-Pell arc lamp. Opinions of the press regarding the lamp are also given, as well as excellent testimonials from a number of prominent members of the electrical profession, including Prof. George Forbes, Prof. S. P. Thompson, Mr. W. H. Preece, and Mr. W. Lant Carpenter. A list of the principal users of the lamp is added, amongst them being several of the British Government Departments; the Governments of New South Wales, South Australia, Germany, Russia, Italy, and Japan; the Corporations of Leeds and Blackpool; large towns in the Colonies, &c.; societies and colleges; several of the British railway companies; dock and harbour boards; steamship, telegraph and mining companies; electric supply companies' lighting stations, including the Metropolitan, London, Liverpool Manchester, House-to-House, Chelsea, Brighton and Hove, Chatham, Rochester and District, Eastbourne, Keswick, Berlin Elektricitäts-Gesellschaft, Hong Kong, Shanghai, and the River Plate Companies. A lengthy array of electrical and miscellaneous companies and firms, and theatres using the Brockie-Pell lamp, concludes what is undoubtedly a very influential list. The catalogue also contains illustrated descriptions of special fittings made by the firm; and some useful tables are given, comparing the electric light with gas, oil, and candles, both as regards brilliancy and as affecting health.

Messrs. Paterson and Cooper.—We are in receipt of the newly-issued catalogue of dynamos and electric lighting apparatus of this firm, containing a revised price list of the various sizes of

Digitized by Google

the Phœnix dynamos for arc lighting, copper refining and electro-deposition, electro-plating, steamship lighting, &c. Particulars are also given of combined and inverted engines and compound-wound Phœnix dynamos, as well as of combined single-acting closed engines and compound-wound Phœnix dynamos, accompanied in each case by figures. An illustration is also given of the Gwynne-Cooper dynamo, which is a directly-coupled engine and dynamo, for which it is claimed that, owing to the small space taken up, the arrangement is specially suitable for ship lighting, or where space is limited and valuable. The catalogue likewise contains illustrated descriptions and revised prices of the Phœnix differential arc lamps and of the Phœnix carbons. A number of useful tables are also given, and the catalogue concludes with some flattering testimonials from firms who have used for some time the dynamos and electrical apparatus made by Messrs. Paterson and Cooper. We may mention here that a small installation put down by Messrs. Paterson and Cooper can be seen at work at the Exhibition now being held at the Agricultural Hall, Islington, N.

BERNSTEIN ELEKTRICITÄTSWERKE.—Mr. Alexander Bernstein informs us that he has sold his business and works at Hamburg to a private company, who will trade under the above title. The change has been necessitated by the increased demand for the specialities made by the firm.

THE UNIVERSAL TELEPHONE COMPANY.—We are informed that Messrs. Daniel Judson and Son (Limited) have disposed of their telephone business to Messrs. P. P. Kipping and Co., trading as the Universal Telephone Company. The new company have taken the offices recently vacated by Messrs. Woodhouse and Rawson, at 11, Queen Victoria-street, E.C., and announce that they are prepared to estimate for all kinds of telephone work.

COMPANIES' MEETINGS & REPORTS.

The New Australian Electric Company.

The first half-yearly meeting of shareholders in this Company was held on January 31st at the City Bank Hall, Melbourne, Victoria.

Prof. Kerenot occupied the chair, and submitted the report of the Directors, which contained the following information:—

As the result of the transactions for the last six months, there remains a net profit of £1,942. 9s. 9d., out of which it is proposed to pay a dividend at the rate of 10 per cent. per annum, leaving a balance of £1,068 8s. 3d. to be carried forward. In accordance with the objects for which the Company was formed, your Directors purchased the business of the Australian Electric Company (Limited), as a going concern, for 8,382 fully-paid shares in this Company, and undertaking to discharge all its obligations, taking it over as and from July 1, 1889. The plant so acquired was of the highest value, being of modern type and in first-rate order, and in the hands of the new Company is being fully utilised with highly profitable results, enabling a dividend to be declared for the first six months. In view of the rapid advancement of electric lighting, and in order to meet the demands of the numerous applicants for the light in Melbourne and suburbs, and to fulfil lucrative contracts, the Directors determined to largely increase their lighting power, and therefore purchased on favourable terms a piece of land upon which they could erect a new lighting station and factory, comprising about two acres, situated at Richmond, close to the South Yarra railway bridge, adjoining the railway, and having a river frontage, thus providing an abundant and inexpensive water supply for the machinery. It is likewise the centre of a most important lighting area. They were further able to purchase upon exceptional terms a most complete and modern arc and incandescent plant with engines and boilers, just landing in Melbourne. Both buildings and plant are being arranged so that additions can be made from time to time to keep abreast of all demands until the whole of the ground is covered. The Directors have effected important changes in the management. Captain Rowan, formerly Managing Director, resigned his position, and also retired from the Board. The offices of the Company were removed to the lighting station at Russell-place, and other changes have been made, effecting a saving of over £1,000 per annum in working expenses. As the Board is of opinion that a Managing Director is unnecessary, you will be asked to amend the Articles of Association, and abolish that office, as at present it is mandatory that there should be one. The Directors feel assured that the New Australian Electric Company (Limited) having been started under such favourable auspices, and having secured a most valuable property at a great bargain, has a successful future before it, and presents a highly promising field for investment. Fresh capital is needed for the erection and completion of new plant and the extension of business in portions of the city and suburbs not yet provided with electric light. The first issue of 30,000 shares not being yet fully subscribed for, the balance, amounting to 13,031, is now offered to shareholders—terms: 5s. on application, and 5s. on allotment—and immediate application is necessary, as they will be allotted in order of application.

The CHAIRMAN, in moving the adoption of the report and balance-sheet, said that electric lighting had been rather a drag on those who had invested in it, but the time had come for a change. This was a new Company, formed on a different basis from the old one, and free from many of its disadvantages. As to the dangers of electric lighting, he pointed out that there was danger in connection with gas or anything else until people became acquainted with its use. Even at present accidents from gas were of frequent occurrence. In America there had been deaths caused by electric currents, but these were due to carelessness in fitting up and working. High-tension currents had been in use in Europe for years past, but it was only in America that deaths had taken place. In London a high-tension current far stronger than that which would be adopted here had been in use for four years over several miles, and not a single accident had been reported. These currents were also in use in Rome, Milan, and Vienna and elsewhere, without causing deaths or injuries. This Company was not going to run any risk, and would use only the best materials, and employ the best men and take every reasonable precaution in fitting up. Their experience was that they could use high tensions with perfect safety. They had in their possession about 60 miles of special wire of a costly description, made expressly for the purpose of conveying currents with safety. The scare about danger from electric lighting was plainly due to work being badly and cheaply done, and without proper precautions. With the proper precautions electricity was as safe as anything else. The Richmond Council had adopted the electric light for the street lamps, and this company would supply it, the cost being rather less than that of gas.

Captain ROWAN seconded the motion. He stated that his retirement from the position of Managing Director did not indicate that he was out of sympathy with the policy of the Board. There were certainly differences of opinion, but their policy was being carried out on a sound basis and the outlook was decidedly good. He mentioned that the Brush Company had thought it worth while to repurchase the whole of their Australasian patents, and intended to push them, having every confidence in the future of electric lighting in these colonies.

The report was adopted, and a motion to declare a dividend of 10 per cent. was agreed to.

Prof. Kernot, Mr. J. F. Levien, and Mr. B. J. Fink, the retiring Directors, were re-elected. Mr. F. A. Wilson was re-elected auditor.

The Articles of Association having been altered to the extent of abolishing the office of Managing Director and removing all consequential references to that office, the meeting closed.

The Newcastle Electric Supply Company (Limited).

This Company held its first annual meeting at its offices, 1, St. Nicholas-buildings, Newcastle-on-Tyne, on Monday afternoon last.

The Directors reported that since they met the shareholders in May last the Company have erected a building in Pandon Dene, in which they have placed two boilers and two engines of 200 horse-power and two dynamos. The Company was prevented by unforeseen difficulties with regard to the Board of Trade licence from commencing to lay their cable until December 11th last. Since that date they have laid 5,400 yards of pipes, with 125 junction boxes, and drawn in 1,600 yards of cable, besides 300 yards of temporary cable on ground not yet ready for permanent work. The work of actual lighting was commenced on January 31st last, and at the present time the Company is daily supplying current for 800 ten-candle lamps. Contracts have been entered into equivalent to about 2,500 ten-candle addititional lamps, which will be brought into work as fast as the necessary wiring of the premises can be completed. Negotiations are pending with many persons who contemplate using the electric light. The Directors report that they have agreed with the Newcastle and District Electric Lighting Company (Limited) for a division of the electric lighting work to be done in this city. Roughly speaking, this Company takes the eastern half, and the other company the western half. The capital of the Company, £15,000, which comprises the first issue, has been fully subscribed for, of which £12,000 has been called up (including £1 per share payable on the 24th inst.), and it is not intended to make any further call on these shares. But the Directors being of opinion that the demand will overtake their present power of supply before next winter, have determined to extend the buildings and to lay down a third set of plant. They further think that some provision of working capital should be made for indoor wiring work which it is desirable the Company should be prepared to undertake when required, and altogether they consider that the expenditure of a further sum of £7,000 is desirable. The Directors have made arrangements for the provision of this money. The Directors recommend that the number of Directors, which is at present seven, be increased to nine.

The report and accounts were adopted and approved, and it was resolved to increase the number of Directors to nine.

The whole of the retiring Directors were re-elected, and Colonel Sheppee, of the Birtley Iron Company, and Mr. James Knott, shipowner, were elected additional Directors.

The Telephone Company of Egypt (Limited).

The following is the report of the Directors for the year ended 31st December, 1889, to be presented at the seventh ordinary general meeting of the Company, to be held at the registered offices of the Company, 14, Austinfriars, E.C., on Tuesday, the 25th inst., at 12:30 p.m.

After writing off a sum of £250. 2s. 11d. for depreciation, and providing for the interest on debentures, the net profit for the year is £4,011. 0s. 5d. Adding to this amount the sum of £1,069. 6s. 11d. brought forward from 1888, the balance available for disposal is £5,080. 7s. 4d. Out of this the Directors recommend a dividend of 6 per cent. for the year on the Preferred shares, free of income-tax, which will absorb £3,621. 6s., leaving £1,459. 1s. 4d. to be carried forward.

The amount brought into the credit of revenue account in respect of subscriptions and rentals shows but a small increase over the previous year. This is due partly to a falling off in the number of subscribers connected during the year, and to the elimination of some overdue subscriptions, the realisation of which the Manager reports as doubtful.

A further growth of the exchanges at Alexandria and Cairo does not appear probable for the present, and the Directors are therefore endeavouring to extend the use of the telephone to other towns in Egypt.

They are glad to be able to announce that an exchange was opened at Port Said on January 28th, and, according to the latest advices received, twenty subscribers had been connected. The manager anticipates that before the close of the current year this number will be materially increased. The Directors hope also to be able to establish a small branch at Assiout during the next few months.

Under the Articles of Association, Mr. Thomas Lloyd retires from the direction, but being eligible offers himself for re-election. Messrs. Price, Waterhouse, and Co., the auditors of the Company, also retire, and offer themselves for re-election.

NEW COMPANIES REGISTERED.

ELECTRICAL ENGINEERING COMPANY OF IRELAND (LIMITED).—This Company has been formed with a capital of £50,000, divided into 24,950 ordinary shares of £2 each, and 100 founders' shares of £1 each, with power for the Directors to borrow to the amount of £15,000. The electrical engineer to the Company is Arthur E. Porte, A.I.E.E., and the secretary (*pro tem.*), J. Buckley. The consulting engineers are John S. Raworth, M.I.E.E.; R. Percy Sellon, M.Inst.E.E.; W. G. Strype, C.E., M.I.C.E., M.I.M.E. The temporary offices of the Company are at 46, Dame-street, Dublin.

FOREIGN AND COLONIAL ELECTRICAL POWER STORAGE COMPANY (LIMITED).—This Company has been formed with a capital of £100,500, in £5 shares, to acquire certain foreign and colonial patent rights for inventions relating to the storage and supply of electricity by batteries or accumulators upon the principle known as the "E. P. S." system. It is proposed to purchase these rights from the Electric Construction Corporation (Limited), of Worcester House, Walbrook, E.C., and Wolverhampton, who now hold them, and who are the promoters of the Company, for the sum of £75,000, payable in cash or shares at the option of the Company. One hundred of the shares are founders', which will receive no dividend in any year until the ordinary shares have received 8 per cent. for that year.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended March 14th amounted to £4,644.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—We have received a note from Mr. G. Binswanger announcing that he has resigned his seat on the Board of this Company. In his note he reminds the shareholders of the Company that he was elected to represent the interests of the creditors of the old Company who exchanged their claims for shares in the new Company. As the issue of the remaining shares has been successfully accomplished, Mr. Binswanger considers his task at an end. In regard to the reference made by Mr. Binswanger to the subscription of the capital, last week the Company effected a new issue of 37,723 Ten per Cent. Preference shares of £1 each, making the capital of the Company £70,000, in 70,000 shares of £1 each, of which 50,000 are Preference shares and 20,000 Deferred shares. These latter are not entitled to any dividend until 10 per cent. has been paid to the Preference shareholders, and any surplus is to be ratably divided between the Preference and the Deferred shareholders. The Preference shares are also entitled to priority in respect of capital in the event of any sale or liquidation of the Company's assets. Out of the total of 70,000 shares 37,000 have been applied for by the Directors and their friends. It is proposed, out of the present issue, to pay off £16,000 of Ten per Cent. Debentures. This will give the Company an additional working capital of £21,500, of which it is intended to leave about £13,000 uncalled, to meet future contingencies. The Company confidently anticipate being able, after allowing for depreciation and other expenses, to pay 10 per cent. on the Preference capital. The prospectus of the new issue notifies that the Gülcher Company is one of the few electric light companies of the many formed in 1882 which have survived to the present day. It has a sound and increasing business, first-class plant and machinery, and an experienced and skilled staff of officers and workmen, and the dynamos and other manufactures of the Company are among the few that have been accepted by the British Admiralty Department.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.—The traffic receipts of this Company for the week ended March 14th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,485.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended March 15th were £3,502, showing a decrease of £126 as compared with the corresponding period.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

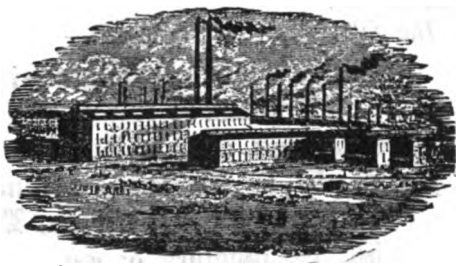
This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.



FLEXIBLE, 2/- per lb. | HARD, 2/3 per lb.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 619.—Vol. XXIV. FRIDAY, MARCH 28, 1890. Price Fourpence.

NOTES.

The long and animated discussion at the Institution of Electrical Engineers, which followed the reading of the Papers of Messrs. Swinburne and Esson, will compare in interest and general importance with that which arose in connection with the subject of transformers two years ago. Although the Papers and the subsequent discussion were devoted more especially to the details of dynamo construction, yet, as was pointed out by Prof. Forbes, electrical engineering has now reached a stage at which the study of these minor points is all that remains to be done.

The Papers and discussion were remarkable for the numerous empirical rules suggested for practical use as the result of experience. There does not appear to be any satisfactory means of calculating the performance of large machines from observation of small machines of a similar type. On the other hand, several speakers bore witness to the possibility of calculating the magnetic leakage, occurring in dynamos, with sufficient accuracy for practical purposes. In connection with this subject, a very simple method of plotting the lines of force in the neighbourhood of dynamo machines was described by Mr. A. P. Trotter.

Some discussion took place on the advantages and disadvantages of the term "magnetic resistance." The President objected to it, firstly, because it did not represent waste energy, and, secondly, because it was not constant. The first objection was pointed out some time since by Mr. Oliver Heaviside, who, in consequence, proposed to substitute the phrase "*magnetic reluctance*." The second objection might, as has been pointed out in our correspondence columns, be made with equal force against the custom of talking of the "resistance of an incandescent lamp." The use of some such phrase as "magnetic reluctance" is the natural outcome of Mr. Kapp's celebrated Paper on the magnetic circuit, which is acknowledged to have much simplified dynamo design. Whether the term adopted is "resistance" or "reluctance," or any other, is a minor matter.

The supremely important question whether motors and dynamos should differ radically in design, although carefully avoided by some notable speakers, gave rise to several most emphatic expressions of opinion. Indeed, so emphatic were these expressions of opinion that they have called forth a protest from Prof. Perry, who, in a letter which we print in another column, takes exception to the epithet "nonsense" as applied to his and Prof. Ayrton's theory of motor design. The language used by some of those who took part in this debate certainly could not be accused of want of vigour; and although the discussion consequently gained in piquancy, its practical value was not greatly enhanced. So far from crying "peccavi" on the question of motor design, Prof. Perry, it will be seen, is astonished at the soundness of the views held by himself and Prof. Ayrton on this subject so far back as 1883.

The experiments of Prof. Ayrton on Immisch and other motors certainly tend to show that the strength of the field in which the armature revolves is increased by the armature reactions; and these views were confirmed by Mr. A. T. Snell, who pointed out several differences between motors and dynamos, and stated that it was possible to get a greater output from a given machine when run as a motor than as a dynamo. The balance of opinion was, however, decidedly in favour of the view that, although the armature reactions in the motor may in some cases increase the field strength, the best results in practice were to be obtained by arranging, as in a dynamo, so that the armature field opposed the induction due to the field magnets.

At the Royal Society on Thursday last Prof. Schuster read the Bakerian lecture on "Conduction in Gases." The Paper, which was one of great originality and power, put forth some new theories, supported by many novel facts, some of which had been previously brought to the notice of the Society by the author. Four different causes for electric conduction in gases were distinguished, arising from the heating of the electrodes, the action of ultra-violet light, the action of flames, and the phenomena of electric discharge, as in vacuum tubes. A new theory was advanced to explain the origin of the dark space in vacuum tubes, and the distribution of the electrified particles was discussed. Another matter brought forward was the fall of potential within the tube. The form of the potential curve obtained was found to be the same for every density, and the conclusions arrived at were that the negative pole was surrounded with positively-charged particles; and that, in order to account for the passage of electricity, it was necessary to assume that about one molecule in every million is decomposed into its constituent atoms. A proof was also given that the quantity of electricity carried by the atoms in the discharge is of the same order as those carried in electrolysis.

Those who were fortunate enough to gain admission last Friday to the Royal Institution to hear Prof. Fitzgerald lecture on "Electro-magnetic Radiation," a report of which will be found in another column, witnessed an exhibition of experiments which have hitherto only been performed in comparatively few laboratories. All Hertz's chief experiments were repeated, and the electric oscillations were made visible to the large audience by means of the simple galvanometer method of detection, discovered by Prof. Fitzgerald, and described in our editorial columns two or three weeks back. Reflection by plane and parabolic surfaces, polarisation, and interference, were all experimentally demonstrated in connection with electric undulations. The shape and movement of the electric waves were vividly shown by means of lantern projections on the screen. In order to make the figures blend successively into one another and present a continuous progressive appearance, an ingenious modification of the zoetrope was employed, designed by the learned Professor, who humorously gave it a name far too long to print. One very interesting and important result of the electro-magnetic theory is that the electric energy radiated from an origin of alternating currents is for the most part returned. Only the portion which gets beyond a range of a quarter of a wave-length, and which in all practical cases is insignificant, is really lost. Thus, with an alternating-current dynamo running at a speed corresponding with 100 periods per second, the wave-length is about 2,000 miles, and the amount of energy lost by radiation corresponds only with the electric forces exerted by the dynamo at one-quarter of this distance, viz., 500 miles, and is thus quite negligible. The bulk of the radiated energy travels backwards and forwards over the immense distance of 500 miles 400 times in every second. It would have been interesting to learn what proportion this radiated energy bears to the output of the dynamo; but this, of course, was not within the scope of the lecture, which, indeed, left out of account altogether the transmission of energy by conduction.

In an interesting article in the current number of the *Nineteenth Century*, Prince Kropotkin gives us his views on the subject of "Brain Work and Manual Work." Technical education, in the ordinary acceptation of the phrase, he will have none of. The reproach of waste of time which is brought against workshop apprenticeship is, he thinks, equally applicable to those technical schools which endeavour at once to teach some special handicraft. For specialism in manual and scientific training, Prince Kropotkin would substitute systematic instruction in the fundamental methods which underlie all handicrafts, and in the fundamental ideas which underlie all sciences. With this groundwork of theory and practice he anticipates that the worker will soon specialise for himself, and will succeed all the better for not having been from the commencement kept in a comparatively narrow groove. The article is evidently written throughout under the impression that the sole object we have in view in this country in founding technical schools is the highly laudable one of turning out men capable of competing with the foreigner. That this is the origin of the support given by the public to technical education we have but little doubt; but many of its most ardent advocates are animated quite as much with the desire of raising the manual worker to a higher level, as with what the author of the article loftily terms "the shopkeeper's view" of the question."

The choice of Chicago as the site of the next World's Fair has of course given rise to considerable jubilation in "the most liberal, practical, and active city in the world." Although we are unable to endorse all the superlatives so lavishly employed in this connection, or even to go so far as our esteemed contemporary the *Western Electrician*, and assert that "the World's Fair of 1892 or 1893 will doubtless be the most important international exposition ever held, and the Electrical Exhibition will be its crowning feature," we shall indeed be surprised if Chicago, with the manifold advantages it possesses, fails to make its Exhibition at least compare favourably with that held last year at Paris.

We are glad to be able to inform our readers that the problem of successfully applying electricity as a motive power to vehicles has at last been solved. As our readers are aware this problem has occupied the minds of inventors for some time past. Electricians have generally declared the use of a primary battery impossible for this purpose; but it is needless to say that electricians are all wrong; a primary battery *has* been discovered, and the "principle" has been applied—so at least we gather from the *Citizen*—to bath chairs, pleasure boats, and tricycles, and, within a limited period, tramcars, carriages, and trains will fall victims to the new power. An invention of this magnitude has, of course, an immense future; and when primary batteries are employed to drive tramcars at least one revolution may be predicted.

We have learnt from Sir William Thomson that the current in Lord Armstrong's experiment was direct, and not alternating, as inadvertently stated in our notice of last week. We shall be able next week to present our readers with an abstract of Sir William Thomson's Paper before the Royal Society of Edinburgh, wherein the theory of this experiment is discussed.

Richmond (Victoria).—The municipality of Richmond, an important suburb of Melbourne, have decided that their streets shall be lighted by electricity.

Electrical Execution.—The New York Court of Appeals has decided that the law providing for the electrical execution of murderers instead of hanging is constitutional.

Port Melbourne (Victoria).—At a recent meeting of the Port Melbourne Council, it was moved "that steps be taken to have the streets of the borough lighted by electricity." The motion was carried.

Kensington Vestry.—At the last meeting of this Vestry the report of the Special Purposes Committee, recommending that the electric light be installed at the Town Hall at an estimated cost of £286, was adopted.

Royal Society.—Among the Papers down for reading at the Royal Society yesterday was one by Prof. J. J. Thomson and G. F. C. Searle on "A Determination of 'v,' the Ratio of the Electro-magnetic Unit of Electricity to the Electrostatic Unit."

Digitized by Google

Brussels.—The Brussels Tramway Company has decided to stop at the end of April the three accumulators which have been running for the past four years in the Rue de la Loi. The reason for the step is said to be the loss entailed by this system of traction.

City of London and Southwark Subway Railway. — The Bill promoted by this Company passed Committee on Friday last, a clause for the protection of the London, Chatham, and Dover Railway Company in the matter of the Clapham-road Railway Bridge being inserted.

Instantaneous Photography by the Electric Spark.—At the recent conference of the Camera Club, Lord Rayleigh gave an account of instantaneous photography by the light of the electric spark, and exhibited photographs of jets of water taken in less than the 100,000th part of a second by this means.

Electrical Engineering Courses.—The electrical engineering class at the Pitlake Institute, West Croydon, which is presided over by Mr. W. Perren Maycock, has been so well supported that it has been decided to hold a fresh term. There is a similar class at the Whitgift Grammar School, of which Mr. Maycock is also instructor.

Fulham Vestry.—At a special meeting of this Vestry, held last week, it was decided by 17 votes to 9 not to apply to the Board of Trade for a Provisional Order to enable the Vestry to supply electricity. At a previous meeting of the Vestry a proposal to provide the Town Hall with an electric light installation was referred back to the Lighting Committee by 9 votes to 5.

The Pollak Battery.—A primary battery for domestic lighting has been brought out by M. Pollak, which is without porous pot. The electrodes are of zinc and lead respectively, and the electrolyte is a solution of copper sulphate. The zinc dissolves and copper is deposited on the lead plate. As the makers replace the battery plates, when they are exhausted, only the copper crystals have to be paid for.

Telegraphing the Result of the Boat Race.—The result of the Oxford and Cambridge boat race, which was finished at 5:6½ p.m., was signalled to New York by the Direct United States Cable, and reached that city at 5:8 p.m. Greenwich time, and was communicated to the Press by telephone a second later. The transmission between Mortlake and New York only occupied one and a-half minutes, and was not equalled by any other Cable Company.

Institution of Electrical Engineers.—The students of the Institution met last Friday at the Sanctuary, Mr. W. M. Mordey in the chair. Mr. Wightman read a paper on "Constant-Current Regulators." A short discussion followed, in which the Chairman, Messrs. Cirlo, Barton, and Bone took part. After giving a vote of thanks to Mr. Wightman for his Paper and to Mr. Mordey for presiding, the meeting terminated. At the next meeting, to be held April 11th, Mr. G. Müller will read a paper on "House Telephones."

Presentation to Mr. Holland Dell.—On Friday evening last a handsome testimonial was presented to Mr. Holland Dell, who was for eight years secretary to the now defunct Electrical Power Storage Company. The testimonial consisted of a fine black marble timepiece, a purse of money, and an artistic illuminated address, and was presented to Mr. Dell by his old colleagues and business friends as a token of their esteem and goodwill. Mr. Dell is now acting as British and Colonial representative to Messrs. Lacombe and Co.

A Correction.—In our last issue, on p. 490, Mr. Harry E. Jones, of the Commercial Gas Company, is reported to have said, "He thought electric lighting companies had taken the cream of the lighting from the gas companies." Mr. Jones now writes us that he made no such statement. What he did say was that "to the extent which they develope he was of opinion the electric lighting companies, *to a certain extent*, take the cream of the gas companies' business away from them," following up this by the statement reported in our Note, that electricity does not compete with gas except for a luxurious style of lighting.

Ferranti String Band Smoking Concert.—On Thursday evening, the 20th inst., a smoking concert was held at the Sir John Falstaff Concert Hall, Old-street, E.C., by the Ferranti String Band, at which about 600 of the engineering staff and *employés* of S. Z. de Ferranti and of the London Electric Supply Corporation (Limited) were present. Many of the engineers of several of the more prominent electric lighting companies of the metropolis were present. The occasion was taken to present Mr. Sparks (Mr. Ferranti's partner) with a handsome address and a tea and coffee service from the united engineers' staff and *employés* of the above firms on the occasion of his approaching marriage.

The Electrolytic Preparation of Aluminium.—The Pittsburg Reduction Company, who are now among the largest producers of aluminium, prepare the metal by electrolysing a bath of Al_2O_3 dissolved in molten aluminium fluoride, the solvent suffering no loss in the operation. The current is conveyed to the bath by carbon cylinders, which form the positive electrode, a carbon-lined pot forming the negative. The oxygen of the alumina goes off at the positive electrode as carbonic acid, wearing away the carbon at the rate of nearly a pound of carbon per pound of aluminium produced. The reduced metal settles to the bottom of the pot, from which it is easily tapped or ladled off, practically free from the electrolyte.

The Thomson-Houston Electric Company.—Some idea of the magnitude and rapid growth of this company may be gathered from the following figures, published by the *Financial News Bureau* of Boston. The company's net earnings last year amounted to over $2,000,000. The authorised common capital of the company is $10,000,000, of which $4,500,000 have been issued. The authorised amount of the Preferred stock is $5,000,000, of which $1,000,000 was issued in July last. The annual business of the company is now in excess of $10,000,000, the net income per month amounting to $250,000. The company employs 2,500 hands at its factory in Lynn, and a force of 150 men at its Boston office. The Lynn pay-roll amounts to $27,000 per week.

Electric Launches at the University Boat Race.—A distinguished company assembled on board the electric yacht "Viscountess Bury," at Messrs. Immisch and Co.'s charging station, Mortlake, to witness the finish of the Oxford and Cambridge Boat Race on Wednesday last. Amongst those present were Viscount and Viscountess Bury, the Hon. Hilda and Mrs. Keppel, T.S.H. Prince and Princess Victor of Hohenstche, the Countess Gleichen, Lord Wantage, Sir Henry Mance, Mr. Irving Courtenay, Prof. and Mrs. George Forbes, Mr. Joseph Smith, and many others. Prior to the advent of the crews a number of very agreeable trips on the smaller launches, "Alpha," "Beta," "Gamma," "Delta," &c., were arranged for the visitors, who expressed great satisfaction at the handiness and steadiness of the boats, which were undoubtedly a feature of great interest to the mass of onlookers present. Messrs. Immisch are to be congratulated upon the success of the arrangements made for the large company assembled.

The Alternate-Current Transformer System in Italy.—We are indebted to the *Bulletin International de l'Electricité* for the following list of Italian central lighting stations on the alternate-current transformer system :—

	Motive Power.	System.	Capacity in kilowatts.

Newcastle.—At the last meeting of the Town Council reference was made in the report of the Watch Committee to the offer of the Newcastle and District Electric Lighting Company to place 1,500 candle power arc lights in the open spaces at the Central Station and Cattle Market at the same price as the Corporation paid for the gas; the Committee proposed to experiment with these two large lamps, and if the experiments were successful, arrangements would be made for extending the use of the electric light. This would necessitate the extinguishing of a number of gas lamps, and therefore the Committee was of opinion that it would be much better to be freed from the restrictions imposed by the Gas Company; and they recommended that the 7½ per cent. discount offered under certain conditions by the Gas Company be declined, so that the Committee might be free to light the streets in any manner they pleased. The report was adopted. The cables now laid underground by the Newcastle and District Electric Lighting Company are sufficient to supply 5,200 10 candle-power lamps. There are in all 14,200 yards of cable laid.

Edinburgh.—A conference was held at Edinburgh on Tuesday between Lord Balfour of Burleigh and Mr. Courtney Boyle and a deputation of the Edinburgh Town Council on the subject of electric lighting. The Lord Provost said the Corporation was anxious to keep the management of the whole thing in their own hands. They contemplated applying for a Provisional Order as soon as possible, and would have done so before, but there was some doubt as to who was the local authority under the Act. Lord Balfour of Burleigh said that, as far as Edinburgh was concerned, there was no further doubt as to who was the local authority. Mr. Courtney Boyle said he thought the companies, if they had to wait till next spring, ought to be given some preference by the Corporation over any other companies coming forward later. The Conference then proceeded to consider in private the clauses of the Electric Lighting Amendment Bill. Later in the day representatives of the Scottish Electric Supply Company and the Scottish House-to-House Supply Company had a conference with Lord Balfour and Mr. Courtney Boyle. Mr. Graham Murray, for the former Company, pressed for an inquiry, the date of which might be postponed until the Town Council had decided what to do. Mr. Colquhoun, of the latter Company, pressed for an immediate inquiry, if any. At the conclusion of a lengthy discussion, Mr. Courtney Boyle said that it might be possible that the Town Council, in taking up their present position, really represented the views of the ratepayers, who, perhaps, did not want the electric light at all.

Electricity in Wine Vaults.—The offices and champagne vaults of MM. Chandon et Cie., at Épernay, have recently been provided with a very interesting electric light and power installation. The plant comprises three Babcock and Wilcox boilers, three 60 horse-power Bréguet engines, and six dynamos. Three shunt-wound 12-unit Bréguet machines supply the current for the incandescent lighting and storage batteries. Two compound-wound Manchester machines, giving 250 volts and 55 amperes, supply the current for power purposes, and arc lights are run off a third Manchester dynamo (70 volts × 200 amperes). The incandescent lamps are mostly of 16 candle-power, and in the overhead portion of the establishment are fixed in the ordinary manner. In the vaults the wires are bare and of silicium bronze, the lamps being attached to the wires wherever wanted by flexible connectors. The fall of potential in the circuits near the dynamos is limited to two volts; but in those feeding the distant vaults and outhouses a maximum loss of 12 volts is allowed for, the E.M.F. of the dynamos being regulated by varying a resistance in the shunt-circuit. The motors, which are of the Raffard type, with Pacinotti-Gramme armatures, are used for a variety of purposes, such as working lifts, pumps, bottle-rinsing machines, &c. Several champagne establishments are putting in electric light and power plants, owing to the many advantages attaching thereto, such as reduction of temperature in the wine vaults, and the time saved by employing electric motors in the various operations of champagne making and bottling. MM. Chandon et Cie., we should add, have nearly 10 miles of underground vaults.

Gulcher's Thermo Battery.—Mr. R. J. Gülcher, the designer of the Gülcher dynamo, has lately brought out a new type of thermo-electric battery. The electro-positive electrodes are hollow, and consist of chemically pure nickel tubes. Joined to these are the electro-negative cylindrical bars, which consist of an alloy of antimony. Each battery consists of a U-shaped channel resting upon the base, and closed at the top by a slate slab, into which the nickel tubes are fixed in two rows. The top of these tubes is provided with a perforated collar of soapstone, so that the gas which passes up from the U-shaped channel is emitted from these perforations and heats the junction of the two metals directly above the perforators. Above the soapstone collar there is a second one of brass, which protects that part of the antimony alloy connected with the nickel. The negative electrode, which rests on the top of the nickel tube, turns outwardly and downwardly, and is continued in a flat copper strip, which serves as a cooling medium, and also as a connection to the next element. Each element has its own gas outlet and a separate heating flame. As the flames are very small, enough air can get at each flame to effect combustion in the same way as in the Bunsen burner, and as a consequence neither soot nor carbonic oxide gas is formed. The following data are given in the *Elektrotechnische Anzeiger* concerning the consumption of gas and electrical energy developed by a thermopile of 50 elements. The consumption of the battery mounts to about 8 cubic feet of gas per hour. Its E.M.F. is 4 volts, and its internal resistance 0·48 ohm. The manufacture of this battery has been taken up by the well-known firm of Julius Pintsch, of Berlin.

Electricity and Photo-Engraving.—In commercial photo-engraving, zinc etching, and the gelatine relief process, it is absolutely necessary, says the *Electrical World*, that the exposure be properly timed. Any increase in the duration of the exposure will cause what is termed an "overprint." On being placed in charge of the relief gelatine process some years ago, Mr. W. A. Blomgren, of Blomgren Bros., Chicago, found that the best of assistants would sometimes fail to remove the plate at the correct time, causing an annoying loss of time and material: so he devised an electric alarm, which has proved so satisfactory that the company have one connected to each of their three or more copying cameras. The device consists simply of an ordinary clock movement, having a special form of dial with sixty points indicating minutes traced thereon, around which revolves one hand in unison with the movements of the clock, while a second hand, insulated from the other, is moved to any desired point at the will of the operator. Both hands have platinum points that make a rubbing contact when the minute hand passes over the quiescent hand. When an exposure is to be limited to, say, six minutes, the still hand is moved six minutes in advance of the minute hand, and when the latter reaches that point it closes the circuit and causes several strokes of the bell to ring out while rubbing past, and notifying the assistant to change the plate. A further improvement of especial value to the operator temporarily left without an assistant is a small coil and armature placed above the inner face of the lens within the camera, and connected in the circuit with the clock and bell. When the circuit is open, a shutter or blind is lightly supported by the armature of the coil, and is released and allowed to fall on the closing of the circuit, thus preventing further exposure.

Paddington Vestry.—At a special meeting of this Vestry on Friday last, the question of the electric lighting of the parish was considered. Colonel H. C. Barchard proposed the adoption of the report of the Lighting Committee, which recommended that the application of the Kensington and Knightsbridge Electric Lighting Company should be assented to. But if the Vestry considered the draft regulations now being prepared by the Board of Trade to do away with the objections to the high-pressure system, then the committee was of opinion that the application of the Metropolitan Electric Supply Company might be considered. As the cost of lighting the streets with electricity would be very greatly in excess of gas, the committee did not feel justified in recommending it. Mr. H. H. Mills proposed, as an amendment, that the Provisional Order be amended, inasmuch as the draft Provisional Order prepared by the committee did not secure to the ratepayers such advantages as they were entitled to receive as a consideration for the very valuable concession involved in

Digitized by Google

the granting its assistance to a company to obtain an Order for lighting the parish. It was finally agreed to adjourn the further consideration of the matter.—At a second special meeting of the Vestry, held on Tuesday, the report of the Electric Lighting Committee was again under consideration. Mr. Hannay said in the district which he represented (Bayswater) a strong feeling was manifesting itself against the Vestry at the delay which had occurred in this matter, and the inhabitants were very desirous of having the electric light under reasonable conditions. They were about to hold a public meeting on this subject. The Vestry had had the matter under consideration nearly two years, and, as far as he could judge, they were now as far from arriving at a decision as they were at the beginning. Finally, the whole report was referred back to the committee for re-consideration and report.

The Indian Telegraph Service.—The report of the Indian Telegraph Department for the past year shows a surplus of Rs.19,80,245, representing a dividend of 4·45 per cent., which is the highest yet recorded. The principal feature of that year was the increase in the number of private messages, which have gone up from 1,860,390 to 2,115,863, producing a revenue of Rs.22,31,514, as against Rs.19,81,814 in the previous year. The capital expenditure was Rs.17,43,620, raising the total capital of the department to Rs.4,45,21,203. The working expenses were Rs.43,42,231, and the gross receipts, including the value of State messages, were Rs.63,22,476. The actual profits united give a net dividend of 2·15 per cent., as against 1·389 in the previous year, and 0·303 in 1887. The mileage open was increased during 1889 by 1,568 miles, and the wire mileage by 6,137 miles. For field telegraphic operations 105 miles of wire were supplied for the Sikkim expedition and 12 offices opened, 206 miles for Hazara and 23 offices opened, and for the Chin expedition 70 miles, three offices being opened. In the Sikkim expedition a telegraph office was opened which enjoys the distinction of being the highest in the world. It is situated at Bhutong, at an altitude of 13,500ft., nearly two and three-quarter miles above the level of the sea. In the Hazara campaign, ground wires, enabling a temporary line to be rapidly laid, were used for the first time in India, and with such marked success that the Commander-in-Chief expressed special approbation of it, observing that the enterprise with which the line was carried forward with the advance and its efficient working throughout were specially commendable. In regard to accidents, the report states that the total number of stoppages during the year was 1,908, involving 38,729 hours of delay, for 4,105 of which malice was responsible, 2,008 were caused by birds and other animals, 8,107 by falling trees, 644 by lightning, 5,215 by cyclones, and 4,280 by preventable defects in lines and cables.

The Seely Electric Light Cable Connector.—In the jointing of a large number of the underground electric light cables of New York a tubular form of connector has been employed which was designed by Mr. J. A. Seely, of the Seely Manufacturing Company, and which was specially devised to be used in connection with lead-covered cables. The tube, as made for taking off a branch circuit, has the general form of a T, but its parts are slit to facilitate the connection with the wires. The wires when once adjusted are sweated in by solder, which flows into the slits of the joint and forms a solid connection and good electrical contact. The ends of the tube, which abut against the fibrous insulation of the conductors, are double bevelled and rounded to prevent abrasion of the insulation. This obviates a fault in the ordinary T-couplings, which are usually made rough, and it has been found that the square ends are sometimes armed with a burr, which cuts through the insulation, thus admitting water and causing a ground or a short circuit. In the operation of making a connection a section of the lead sheathing is removed from the main. The fibrous insulation is then cut away or tapered toward the middle of the opening, and finally enough of it is entirely removed to expose the length of conductor which is to be covered by the joint. The tube is then passed under the wire and brought up until it surrounds the same, when, by the use of a pair of pliers, it is bent up and around the conductors until the edges of the slit nearly meet. The branch, the end of which has been exposed, is then pushed into the lateral stem of the joint, and the pliers again used, if necessary, to bring up the sides of the tube against the wire. The joint having been placed in position, solder is poured into the slits, which flows around the conductor and makes good contact between the parts, besides sealing the joints. This done, the joint is wrapped with suitable insulating tape or compound. The rounded edges prevent any abrasion of the insulating material. Although specially designed for use in connection with lead-covered cables, the connector is equally well adapted to other conductors, and for general purposes.

Electric Lighting for Railway Stations.—An interesting Paper was contributed by MM. Sartiaux and Weissenbruch to the last Railway Congress, giving an account of the general experience in the electric lighting of railway stations. The authors collected a large amount of valuable information as to the cost of the system, from which we extract a few particulars. The cost of electric lighting is steadily declining, particularly in those items such as interest and depreciation. Even in the matter of maintenance, the expense seems to be decreasing, as is shown by a comparison of two years' working expenses of a 40-light Brush installation at the Waverley Station (Edinburgh) of the North British Railway. With 33 lamps at work for 41,884 hours between July and December, 1884, the total cost was £484. 6s. 6d., or at the rate of 2·77d. per lamp-hour. In the corresponding six months of 1886 the cost of the same number of lamps running 56,174 hours was £411. 0s. 9d., or at the rate of 1·75d. per lamp-hour. The cost of carbons and of the renewal of incandescent lamps is always a heavy item. At the Bebra Station of the Prussian State Railway, it is reckoned at nearly half the total working charges; at the Western Station in Vienna it is 39 per cent.; at Feldkirch 33 per cent.; at Venlo 25 per cent.; on the Northern Railway of France 13 to 24 per cent.; at the Northern Station, Brussels, 10·5 per cent. In spite, however, of the gradual reduction of the cost of electric lighting, and of the high price of gas abroad, a very considerable increase of outlay is required for the former. In all cases, however, there is a greatly increased amount of light. For instance, it is calculated that had the St. Lazare Station in Paris been lighted with gas the cost would have been only two-fifths of what it is, but the light would only have been one-fifth. At Bebra the substitution of electricity for gas has doubled the cost, while the illumination has been increased thirty-fold. The authors made a calculation of the respective values of gas and electricity when used as lighting agents in various ways. According to this, the incandescent lamp of 16 candle-power consuming 50 watts is the equivalent of a gas burner using 5·3 cubic feet and giving 16 candle-light. In these conditions, 1,000 cubic feet of gas equal 8,490 watt-hours. In the Paris Exhibition there were some large burners consuming 157 cubic feet of gas per hour. These probably had a mean intensity of 9 candles per cubic foot, or 1,400 candles in all. A continuous-current arc lamp of this mean intensity would produce a greater illumination on the ground, and would not require more than 750 watts. Under these conditions, 1,000 cubic feet of gas is equivalent to 4,700 watt hours. The price per watt-hour varies with the number of hours of lighting, as is shown by the following figures supplied by the Northern Railway Company of France. At their Calais Station, the number of hours lighting per lamp per annum is 500; the number of lamps of 25 amperes and 45 volts in use, 8; and the price per 1,000 watt-hours, 10·42d. The figures for other stations are as follows:—La Chapelle: Hours of lighting, 1,010; number of lamps, 8; price, 16·3d. La Chapelle sorting station: Hours, 3,582; lamps, 8; price, 5d. Lens: Hours, 5,333; lamps, 7; price, 5·3d. St. Martin: Hours, 3,729; lamps, 6; price, 4·7d. Condekerque: Hours, 3,741; lamps, 4; price, 6·9d. Longueau; Hours, 3,924; lamps, 5; price, 5·4d. Hirsin: Hours, 4,288; lamps, 6; price, 1·46d. The author's calculations, which were embodied in tables and diagrams, show that the cost of incandescent lighting does not fall below that of gas at 4s. 1d. per 1,000 cubic feet until the lighting is prolonged beyond 3,250 hours. On the other hand, with arc lighting in large stations, electricity is cheaper for a given illuminating power than gas at 1s. 7d. per 1,000 cubic feet when the period of lighting exceeds 2,000 hours, and is equal to gas at 1s. 1½d. for 3,000 hours.

MAGNETISM IN IRON AND OTHER METALS.*—XI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 492.*)

§ 54.—Damping and Calibration of the Ballistic Galvanometer.—In some uses of the ballistic galvanometer it is important that there should be little "damping"—in other words, that the swinging of the needle should subside very slowly. But in magnetic observations of the kind now under description—when what we deal with is merely the comparison of different ballistic effects—this is not necessary: it is, in fact, desirable, as a matter of convenience, to have a good deal of damping, provided always there is not so much as to prevent the throws from being proportional to the changes of magnetic induction. To test whether this condition is satisfied, a series of successive currents of increasing strength should be made and broken in the primary coil of § 53, while the corresponding throws are observed and compared with the strength of the primary current, to see that the two vary together. Another plan is to have a small induction coil (in circuit with the ballistic galvanometer) slipped upon a long bar magnet. Pull the coil quickly off the magnet, and observe the throw; then reduce the number of turns in the coil by unwinding one or more of them, and observe the reduced throw when it is again pulled off, and so on, until the number of turns and the throw is greatly reduced. The observed throws should be proportional to the successive numbers of turns in the coil.

To save time between ballistic readings, it is convenient, especially when the damping is not very considerable, to follow Rowland's plan of including in the secondary circuit a small coil slipped upon a magnet.† By pulling it off or slipping it on at the right moment, while the needle is swinging, the observer may, with a little practice, succeed in giving the needle a check, which brings it quickly to rest. Care must, of course, be taken that this coil is not moved while observations are being made.

§ 55. Ballistic Tests of Rings and Rods.—Fig. 23 illustrates the ballistic method as applied to an iron ring. The ring A is

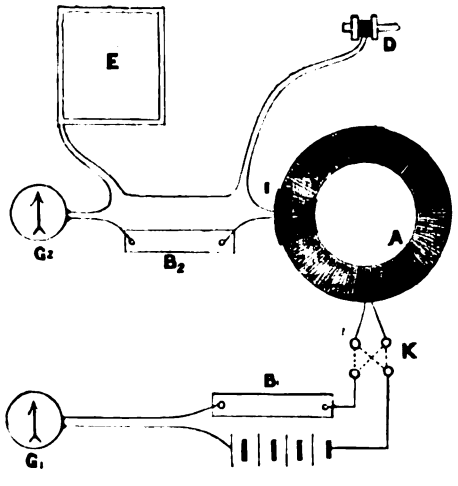

FIG. 23.—Diagram of Connections for Ballistic Method.

wound all over with a primary or magnetising solenoid, the current in which is measured by G_1, and can be subjected to sudden variations by putting in or drawing out the plugs of the resistance-box B_1, or can be made, broken, or reversed by the key K. G_2 is the ballistic galvanometer, in circuit with a secondary or induction coil (wound over a part or the whole of the ring), with the resistance box B_2, by which the amount of the throws may be varied, the earth coil E and the small coil D which is used to check the swinging of the needle. In addition to the parts shown, it is convenient to include in the primary circuit the arrangement of liquid slide and rapid reversing key for demagnetising by reversals, as explained in § 42. By this means we can ensure that the ring is in a magnetically neutral state to begin with.

To test the permeability and determine the force of the magnetisation curve, one or other of two plans may be followed: (1) *By Steps.* A weak current may be applied and the throw noted, then the resistance in B_1 may be suddenly reduced, and the additional throw noted, and so on, each throw measuring the magnetic effect of a sudden increase in the magnetising current. The whole magnetism acquired at any stage is then to be estimated by summing up the throws. The same process evidently allows us to trace the individual and cumulative effects of successive diminutions in the strength of the magnetising current, and thus to trace the magnetisation curve throughout any step-by-step process of applying, removing, or reversing magnetising force. This is its advantage: on the other hand it has the practical drawback that if an error is made in measuring the throw at any step it is carried forward and affects all the subsequent values of the magnetisation. (2) *By Reversals.* Another plan is to suddenly reverse the current in the primary coil. Half the throw is then taken as measuring the actual magnetisation. Breaking the current also allows the permanent magnetism to be calculated by showing the amount that disappears in the withdrawal of the magnetic force. As to the effect of each reversal, care must be taken that the currents are progressively increased, and even then the assumption that half of that effect measures the total magnetism is not quite accurate, especially in the case of hard iron or steel, which is less ready to be magnetised by a force of one sign after a force of the opposite sign has been applied than if the opposite force had not acted. In soft iron the curve of magnetisation as determined by this process of reversals is not materially different from the curve determined by the process of steps.

In applying the ballistic method to long rods or ellipsoids, or other specimens with ends, either of these processes may, of course, be used, and in addition a third plan is practicable—namely, to have the secondary coil arranged so that it may be suddenly slipped off the magnetised piece. The effect of slipping it off is to reduce the lines of induction within it to zero, provided the coil is at once drawn far enough away to get practically out of the magnetic field, and the throw of the galvanometer therefore measures the whole magnetisation which existed just before the coil was removed. This method is often useful, but it must be borne in mind that the mechanical disturbances caused by pulling off the coil may, especially with soft iron, alter very seriously the amount of magnetism associated with any assigned value of the magnetic force. This will be evident later when reference is made to the effects of vibration on the magnetic susceptibility of iron. We cannot, therefore, use this plan to trace the effects of successive currents of ascending and descending strength. After the step-by-step process, however, has been applied to a long rod, slipping off the coil affords a useful test of the accuracy with which the summation of the steps has been carried out.

§ 56. Calculation of B from Ballistic Measurements.—We have seen how the ballistic measurements serve to determine Q, the whole number of lines of induction within the secondary coil. If the secondary coil is wound close upon the iron, very nearly the whole of these lines lie within the iron, and we then have $\mathbf{B} = \frac{Q}{S}$, where S is the area of cross-section of the iron in square centimetres. If, however, the area of the secondary coil includes any sensible air space (or other non-magnetic space) in addition to the iron, a suitable deduction must be made from Q before dividing by the area of cross-section of the iron to find **B**. Thus if the secondary coil is outside the primary, and the mean area of the primary coil is S′, we shall have $(S' - S)\,\mathbf{H}$ lines enclosed within the secondary coil, but outside of the iron, and this number will fall to be subtracted from Q. Even when the secondary coil is wound directly upon the iron, its mean area is necessarily somewhat greater than the section of the core, and there is consequently a small correction to be applied (namely, the difference of these areas multiplied by **H**), but the amount of it is generally insignificant.

ELECTRO-MAGNETIC RADIATION.*

BY PROF. G. F. FITZGERALD, M.A., F.R.S.

The Professor began by explaining how small forces, if repeated at regular intervals so as to give rise to a series of rhythmic impulses, might be made to produce great and destructive effects. By suitably selecting the period of vibration, so as to agree with one of the periods of vibration of any body, these rhythmic impulses might be made to exert destructive effects on that body; and, on the other hand, damage to any given structure might be avoided by selecting periods to which it was incapable of responding. This principle, that certain bodies or structures were capable of absorbing periodic impulses of certain definite periods, being thrown by them into very intense vibration, was known as the principle of resonance. Prof. Lodge, in a lecture on "The Leyden Jar," delivered at the Institution last year, had arranged his apparatus so as to make the period of the alternating discharge as great as possible, in order that each wave might be separately distinguishable. The lecturer then proceeded to explain that for waves in any given medium, which in the case of Prof. Lodge's and his own experiments was the ether, the wave-length was inversely proportional to the vibration period. The length of the waves in Prof. Lodge's experiments was about 600 miles.

Ether waves which would produce the highest audible note would have a length of five or six miles, but what he required for making the presence of electro-magnetic vibration visible was a wave length of from two or three, up to ten or twelve feet. The period corresponding to this would be about the hundred-millionth of a second. Waves giving the highest audible note would take about three hours to make as many vibrations as these would in a second, and the waves in Prof. Lodge's experiments would take about a fortnight.

The lecturer then exhibited a large Hertz oscillator which was to be employed in setting up the electro-magnetic vibrations. This consisted of a pair of large metallic plates suspended from the ends of a long glass rod. From the near sides of the plates projected wires terminating in brass balls, the distance between which was capable of being varied by sliding the plates along the rods. The two plates were then connected with the terminals of a Ruhmkorff induction coil, and sparking set up between them. The indicator employed to detect the presence of electrical oscillations consisted of a long conductor of copper wire, having its ends furnished with brass knobs, brought sufficiently close together to allow sparking to take place between them when electrical oscillations were set up in the wire by the ether waves radiating from the oscillator.

The lecturer then explained the nature of the circumstances which determined the period of the electrical oscillation by comparison with the vibrations of a tuning-fork. The vibration period of a tuning-fork could be diminished either by increasing the stiffness of the prongs, or by diminishing their mass, and, similarly, the period of an electrical oscillation could be diminished by diminishing the capacity of the conductor in which the oscillations took place, or by diminishing the air-space across which sparking occurred; a small electrical capacity in the conductor corresponding to stiff prongs in the fork, and a small air-space corresponding to small mass in the prongs. The sparks in the secondary circuit or detector were too minute to be seen at a distance; but the lecturer was able to indicate their existence to the audience by means of the discovery which he had recently made, that if the air-space terminals were connected through a delicate galvanometer, the galvanometer was deflected whenever sparking occurred across the air-space. He had not at present succeeded in arriving at any satisfactory explanation of this phenomenon, but it afforded a convenient means of demonstrating the existence of the sparks to an audience. The lecturer explained that it would not do to connect the terminals of the secondary circuit, or resonator, as he called it, through the galvanometer, as if that were done no sparking would take place. He therefore had to adopt an arrangement in which a small subsidiary spark was given across an air-space with its terminals connected in this manner.

It was then shown that when the length of the secondary circuit was doubled the sparks became smaller, which was indicated by the diminution in the disturbance of the galvanometer. This result was in contradiction to all the theories of electro-magnetism, with the exception of the Faraday-Maxwell theory that electro-magnetic disturbances were propagated by ether waves. According to this theory it was to be explained as due to diminished resonance, the resonator in the first case having, so to speak, been tuned into synchronism with the oscillator, and the addition of a greater length of wire to the resonator throwing it out of synchronism. The lecturer then illustrated the principle of interference of vibrations by communicating vibrations of large amplitude to the free end of a cord suspended from the roof, and showing, in the first place, that the wave, after travelling up the cord, was reflected on reaching the fixed end, and travelled down again. He then agitated the lower end of the cord rapidly and regularly upon which it separated into segments separated by points of rest, or nodes, and the centres of which were points of maximum amplitude of vibration, or loops. This was explained to be due to the interference of the direct and reflected waves. The fixed end of the cord, or point of reflection, was a node, and the lecturer showed that similarly the point of reflection of an electro-magnetic wave was a node, or point of no vibration. This was effected by placing a sheet of metal immediately behind the resonator, which had previously been sparking under the influence of the oscillator. This reflected the waves, so that the resonator was close to the point of reflection of each wave, and this position was shown to be a nodal one by the fact that sparking at once ceased in the resonator.

The lecturer then referred to Hertz's fundamental experiment demonstrating the existence of a series of points of maximum sparking, or loops, separated by equal distances, each double the distance of the first loop from the reflecting surface. This proved conclusively that electro-magnetic radiation took time for its propagation, as was required by Maxwell's theory.

The lecturer then again threw the suspended cord into vibration, but this time by moving its free end rapidly in a horizontal circle instead of backwards and forwards in a horizontal straight line. This gave to each point of the cord a combined motion of oscillation and rotation which he compared to the electric and magnetic forces respectively in an electro-magnetic vibration, observing that the magnetic and electric forces, like the rotary and oscillatory motions of the points of the cord, were invariably at right angles to each other. It was then pointed out that in the case of a single wave travelling along the cord, the crest of the wave, or point of maximum displacement, was also the point of maximum rotation, while in the case of a series of direct and reflected waves, following each other in rapid succession, the nodes, or points of no displacement, became the points of greatest rotation. It was exactly the same in the case of the electric and magnetic forces, the two attaining their maximum and minimum values together at a distance from the oscillator—that is to say, in the case of a single wave; while near the oscillator—that is, in the case of a series of waves surging backwards and forwards, the magnetic force is a maximum when the electric force is a minimum, and *vice versâ*.

The lecturer then observed that Maxwell had deduced from his theory that light is an electro-magnetic disturbance propagated through the ether, the conclusion that sunlight ought to repel any body which either absorbed or reflected it. The effect, if it existed, would be exceedingly small, which was probably the reason that it had not as yet been possible to detect it; but a similar effect could be observed by suspending a metallic conductor in front of a powerful electro-magnet excited by an alternating current. The conductor absorbed part of the electro-magnetic radiation falling upon it, and also reflected a portion, so that it ought to be repelled by the magnet. This was shown to be the case by suspending a half-crown, with a mirror attached to indicate its motions, in front of an electro-magnet excited by an alternating current from a dynamo in the basement of the Institution. The coin was seen to be repelled as soon as the current was turned on.

Referring to the nature of the ether, or medium by which electro-magnetic waves are transmitted, the lecturer pointed

* Abstract of a lecture delivered at the Royal Institution, March 21.

out that it could not be of the nature of a solid, because rotation could not possibly continue for any long time in the same direction in a solid body; and in the case of the transmission of electro-magnetic waves, continuous rotation of the transmitting medium could go on for hours at a time.

The fact that electro-magnetic radiation obeys the same laws of reflection as the other forms of radiation known to us, viz., light, heat, and sound, was demonstrated by placing a small oscillator with its air-space on the focal line of a vertical metallic parabolic cylinder, and a resonator, in the same horizontal plane, on the focal line of a second metallic parabolic cylinder, having a common axial plane with the former one. The resonator was then seen to respond to the sparking of the oscillator, although the distance was too great for it to have done so without the intervention of the mirrors, and merely by the action of the waves transmitted directly. A wooden frame with a number of parallel wires stretched upon it was then interposed between the two mirrors perpendicular to their common axial plane. It was then found that as the frame was rotated, a position could be found in which the resonator would not respond to the oscillator, but when turned through a right angle it produced no effect, the waves traversing it without hindrance. Now this framework would absorb electro-magnetic vibrations parallel to the wires, but not those at right angles, so that the experiment showed that the electro-magnetic vibrations were polarised—that is to say, were all parallel to one plane.

The growth of the electric and magnetic forces was then illustrated by a series of diagrams, which were first thrown upon the screen in slow succession, and then made to follow one another with great rapidity by means of a kind of zoetropic apparatus, designed by the lecturer, thus illustrating in a very striking manner the nature of a series of electro-magnetic waves.

Returning to the consideration of the nature of the medium by which electro-magnetic waves are propagated, the lecturer exhibited a beautiful experiment to show that a vortex in a liquid could be thrown into vibration exactly as if it were a solid. A large glass jar, full of water, was provided, with a small aperture at the bottom. The lecturer then opened the tap at the bottom, and threw the liquid into rotation about a a vertical axis, by stirring it. A columnar vortex was thus formed, extending from the top to the bottom of the water, and was made visible by throwing some quinine into the liquid, and illuminating it by a beam from an electric lantern. The jar was then shaken, and the beautiful fluorescent vortex was seen to pulsate just like an elastic solid, the waves travelling up and down between the two surfaces of the liquid from each of which they were reflected. The lecturer then suggested that the ether might be supposed to be a liquid containing a number of vortices of this kind, for Sir William Thomson had shown the possibility of the existence in a liquid of stable columnar vortices with their axes inclined at all possible angles. Vortex rings threading between these stable vortices would represent material atoms. This theory would explain all the phenomena of nature as being due to different movements in space.

SWITCHBOARD AND REGULATORS OF THE ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY.

The new switchboard and regulating apparatus now being erected at the Duke-street station of the St. James' and Pall Mall Company has been constructed by Messrs. Latimer Clark, Muirhead, and Co., of Westminster, to the designs of Mr. S. T. Dobson, chief engineer to the Company. The lighting of the St. James' and Pall Mall district is carried out on the three-wire low-tension system, on each side of which the dynamos are run coupled up in parallel. The regulation of pressure is obtained by driving the engines at a constant speed, and varying the resistances in the shunt circuits of the dynamos. The drawings show the front and side elevations of the main switchboard and regulators and below the general plan of connection.

The main board is of massive slate supported by an oak framing on the eastern wall between the two lines of machinery, and is constructed for 12 machine circuits; ten machines having an output of 1,000 amperes each, and the remaining two of 125 each, all the machines being capable of working up to 125 volts pressure if required, for battery work. The connections to the main switchboard from the machines consist of heavy insulated cables, each of one square inch sectional area, carried through porcelain insulators, supported on brackets bolted to the overhead girders.

Following out the circuits on the plan, the cable is carried from the left-hand terminal A of each machine to an automatic cut-out, B, mounted on the top of the machine, and designed so as to break the main circuit when required, the cut-out being held by the current itself, and thrown out by gravity as soon as the current falls to about 30 amperes on shutting down. From the cut-out B the cable is carried overhead to a main fuse-board, C, a line of six main fuses being mounted on a separate board on each side of the large switchboard. A collecting-bar, D, joins each set of six fuses, and these two bars are connected together and led through an ampere-meter, E, to the middle or intermediate main which supplies the six middle mains of the outer circuit. The right-hand terminal F of each machine is connected by a cable carried overhead to one of the 12 terminals G at the top of the main switchboard. From each of these terminals a gun-metal bar is carried vertically down to the switch, one for each machine, and on this bar is mounted a soft iron needle and scale enclosed in a suitable box to form an ampere-meter, H. The lower extremity of the bar forms the top contact of the switch I, the switch itself being built up of copper spring plates to ensure a sound contact. From the lower terminal of the switch the connection is carried down to a stud, J, placed midway between two horizontal bars of copper, K K, L L. From each of these two bars massive copper straps pass up the back of the board, through ampere-meters, M, to supply the six outer pairs of mains. From each of the studs J, placed between the bars K K, L L, a copper strap, N, can be shifted to one bar or the other, and bolted up firm, thus placing any machine on one side or the other of the three-wire system, as required. The use of plugs was abandoned as being unsuitable, for each machine line has to carry up to 1,000 amperes. The connections to the back of the slate are made by means of screwed studs, surrounded by a copper sleeve of slightly greater depth than the slate, so that when the nut and washer are screwed home on the sleeve, a sound contact is made, without bringing any pressure to bear on the slate. All connections are easily accessible from behind.

The machines are all separately excited from the main circuits to ensure quick working. It will be seen that in changing the machines from one side of the system to the other, the currents in the armatures are reversed, owing to one pole being connected permanently to the intermediate main; but the advantage of having only two omnibus bars for a three-wire system is so great, that this object has been obtained by automatically reversing the shunt connections by means of the same connecting straps N on the main board. Thus one end of each shunt, *a*, is connected through a switch, O, placed upon the side of each machine, to the cable leading to the main fuse C. This switch is so constructed that before breaking the field-magnet circuit it throws into parallel with the shunt-coils a non-inductive resistance, P, of German silver wires of equal resistance to the magnet coils, so that on breaking the field circuit the extra current induced discharges harmlessly through this resistance. The other end of each shunt, *b*, is led to its section of the main regulator, and from thence to one of the centre studs J, situated between the two omnibus bars, K K, L L. Thus in reversing the connecting strap N, so as to connect the machine to the right or left-hand outer main, the shunt connection is reversed at the same time so as to magnetise the field coils to suit the change in the direction of the current.

The engines are arranged to run on their centrifugal governors to obtain as far as possible a constant speed; the rest of the regulation is done on a specially designed regulator at the foot of the main switchboard. This regulator is formed of a skeleton frame tied together by two long horizontal angle irons and a fixed steel spindle. Across the angle irons are mounted

SWITCHBOARD AND REGULATOR FOR THREE-WIRE SYSTEM—ST. JAMES AND PALL MALL COMPANY.

Digitized by Google

12 commutator sections, one for each machine, each commutator being connected to a separate resistance of 14 steps for insertion in the field-magnet circuit. On the fixed spindle are 12 rocking handles, carrying, but insulated from, a bent contact piece of copper, which makes connection on the side of each commutator, and a collecting strap parallel to it. The shifting of each handle backwards or forwards puts in or cuts out resistance in that machine. Each handle is fitted with a spur wheel, and on each side of the fixed spindle is a rotating spindle. The back spindle regulates the right-hand side of the mains, the front spindle the left-hand side; and according as the machine is working on one side or other of the mains, the spur wheels are connected by fast and loose pinions sliding on feathers on either shaft to be worked by that shaft. At one end of the regulator two large hand-wheels 15in. in diameter work the two shafts, and in front are the two main voltmeters, not shown in the drawing. The other ends of the shafts are fitted with automatic driving gear, consisting of motors and relays.

The regulating handle for each machine comes directly under the line of connections belonging to that machine on the main switchboard, and the whole of the gear is arranged to obtain the greatest simplicity and symmetry possible. In working the circuit the engine is first started and the brushes put on, the machine being already bolted up to work on one side of the circuit or the other; the exciting switch is then put on and the field excited. Next the automatic cut-out is put up by hand, where it is held in position by a trigger until supported by the main current, and the speed increased by opening up the steam valve, the pressure being noted on a pilot lamp on the main board, placed side by side with a lamp fed from the circuit. A single lamp suffices for use on all the machine circuits, as the contact can be shifted. When the two lamps agree in brilliancy the main switch is closed, and the machine swings exactly balanced on the circuit. The steam valve is then opened up, and the load taken on until held by the governor. The resistance is then cut out of the field coils by the main regulator, and as soon as the machine is doing the same current as the other machines in parallel with it, the regulator handle is coupled up to its spindle, and all the machines regulated together. For shutting down, the resistance is gradually inserted in the field coils, next the engine is shut down until the main circuit is broken by the automatic cut-out, the main switch is shut off, then the exciting current switched off, the brushes raised and the engine shut down.

By having the machines separately excited the connecting rods of the engines may be disconnected, and a small current passed through the armature. The machine will then run as a motor, sufficiently slow and steady to allow of the commutator being faced up by means of a slide-rest bolted on to the bed-plate. The battery plant at the station is separately connected to the mains with its own gear, and is charged by the two smaller machines, which are then cut off the main switchboard by removing their connecting straps. These batteries supply the night lights, and work in and out between the large machines as required, so that every machine when switched in works at once at an economical load by replacing the current previously supplied from the batteries. The whole gear is designed for a quick-working direct system, the Company preferring to rely on the perfection and subdivision of their running plant for a clean record than to sink a large capital in batteries.

LONDON CHAMBER OF COMMERCE.

MEETING OF THE ELECTRICAL AND ALLIED TRADES' SECTION.

At a special general meeting of the Electrical and Allied Trades' Section of the London Chamber of Commerce, held on the 26th inst., at Botolph House, Eastcheap, Mr. Crompton in the chair, it was announced that a letter had been received from Mr. Hammond calling attention to the change which had been made by the Board of Trade at the instance of a deputation from the Municipal Authorities with regard to the power to transfer Provisional Orders. In consequence of this letter the present meeting had been summoned; but in the absence of Mr. Hammond, the second matter on the agenda paper, viz., the proposed formation of a Labour Conciliation Committee, would be taken first.

The CHAIRMAN observed that the question of conciliation in labour disputes had occupied the attention of some of the most eminent members of the Chamber, and that the Section was now asked by the Council of the Chamber to consider whether they should have a Conciliation Committee.

Mr. GRAY observed that his personal opinion was that a Conciliation Committee was of no good, nor were offers of mediation from people who knew nothing whatever about the details of the case of any use.

Mr. MURRAY, the secretary, pointed out that the Conciliation Committee, according to the plan suggested by the Council, would consist of 12 representatives of the employers and 12 of the employed; they could meet privately at the offices of the Chamber, and if they failed to agree they might appeal to a Board of experts, on which both capital and labour would be equally represented; and, failing this, the dispute might be referred to arbitration.

Mr. GRAY replied that the spokesmen who were called representatives did not represent the majority of the employed; they were generally professional agitators.

The CHAIRMAN remarked that the question of real representation was important, and Mr. MURRAY said that they did not propose to deal with professional agitators, but with the representatives of the trades' unions.

Mr. GRAY mentioned names of certain so-called representatives of trades' unions who, in his opinion, were quite unreliable, but they would be bound to deal with them. Another difficulty arose in the working of the proposed plan. If the employed demanded 10 per cent. rise of wages and the employers submitted the question to the Board, the award would probably be a rise, though perhaps less than the full amount demanded. The employers should have an opportunity of stating their own views, that the Board might consider the proposition from each side.

Mr. ERSKINE inquired whether a firm coming to the Chamber with a labour dispute, and coming to no agreement, would be compelled to take the two other steps proposed, and go before the Board of Conciliation; to which Mr. MURRAY replied that nothing would be done unless both parties agreed.

Sir VINCENT BARRINGTON, Deputy Chairman of the Council, here entered the room, and said that the method of conciliation of the Chamber had acted very satisfactorily in the cases of the Medway and of the Oliver Wharf disputes.

Mr. TROTTER said the men were often unwillingly members of the trades' unions. They were persuaded to join while young, as soon as they were out of their apprenticeship, and after they had subscribed for seven years, they felt bound to the union on account of their money which they could not withdraw, and which became a tie sufficiently strong to compel them to act in opposition to their own sense of what was right.

The CHAIRMAN corroborated Mr. Trotter's remarks.

After further discussion, in which Mr. GRAY, Mr. MURRAY, and Sir VINCENT BARRINGTON took part, the latter observed that the men should send non-union representatives; in fact, if they were Irishmen, they should form a non-union union.

The CHAIRMAN then asked what the meeting wished to do. The matter was of great importance to the Section, whose members employed a very high class of labour and many different trades, and their works might be thrown on their beam ends by a dispute arising in a single trade.

Sir VINCENT BARRINGTON said that 45 committees had already been arranged, and that the employers could meet the representatives of the employed at the offices of the Chamber, with no one else in the room.

The CHAIRMAN proposed that a circular should be sent out with the view of forming a Conciliation Committee; and the motion was seconded and carried.

Mr. HAMMOND having arrived, and being called upon by the Chairman said that the Board of Trade had put the supply companies under obligations of not transferring their Provisional Orders, except by permission both of the Board of Trade and of Parliament; and the local authorities should, in his opinion, be under the same obligations. There was careful scrutiny of the applications of supply companies, but there was no such scrutiny for the local authorities. A local authority may apply for a Provisional Order with the object of passing it on to a private company, opposed, perhaps, of gasholders. After giving instances of such applications

Mr. ERSKINE asked whether the rules might not be made so stringent that an Order could not be used for obstruction.

The CHAIRMAN said he did not support a deputation to the Board of Trade, and thought that the only chance of getting the Model Order modified was in Parliament, and suggested that the supply companies who already had a *locus standi*, should be properly represented before Parliament by counsel.

A motion recommending this course was put and carried.

The CHAIRMAN then read a draft of a circular letter, which it was proposed to send to all supply companies both at home, on the Continent, and in America, asking them to co-operate in the mutual interchange of statistical information with regard to the cost of the production of electricity.

Prof. FORBES thought that the Section would get the information from most quarters, but he was doubtful whether they would get it from certain quarters, and if they did he would not believe it.

The motion that the letter be circulated being passed,

Mr. TROTTER reported that the replies of the railway companies to the objections raised by the Chamber on behalf of the Section to the proposed rates had been received, and he had referred them to Mr. Gale. The objections had in several cases elicited an interpretation by the railway companies of points in their classification, which resulted in the advance of the rates asked for by the Chamber; there were two concessions of lower rates, but there were still two or three articles for which the rates proposed by the companies were higher than seemed equitable, e.g., cables which the railway companies said were frequently coiled into and out of the waggons, increasing risk of damage; and steel castings, which were at a rate higher than iron castings. Wood mouldings were rated high as were included in an arrangement with the Master Builders' Association.

The meeting then dissolved.

THE ELECTRIC LIGHTING OF THE CITY.

A special meeting of the Commission of Sewers was convened last Tuesday at the Guildhall for the purpose of considering a report of the Streets Committee relative to the proposed contracts with the Brush Electrical Engineering Company, and the Laing, Wharton, and Down Construction Syndicate, for lighting portions of the City. Mr. Deputy Green presided.

The Streets Committee, while resisting certain proposed alterations in the draft contract, recommended the Commission to concur in the following, viz.:—"That the Company have way-leave in subways for private supply, notwithstanding the contract for public supply may have been determined. That the private supply be exclusive for 21 years, whether the contract for public supply be determined or not. That, as regards the remedy of defects found on inspection, the penalty be not enforced if the work of repair be commenced within twenty-four hours, and be proceeded with diligently to the satisfaction of the engineer. That, as regards the sliding scale, 7½ per cent. per annum be allowed for depreciation, and 5 per cent. per annum for a reserve fund, until such fund amounts to a quarter of the paid-up capital. That though the purchase of the undertaking for public supply at 21 years be under the Act, the purchase of the private supply at 21 years be by agreement or arbitration; the purchase of either at 42 years to be under the terms of the Act. Should your Honourable Court concur in our recommendations, we ask authority also to conclude, on similar terms, with the Laing, Wharton, and Down Construction Syndicate. With regard to the latter Company, we understand that the town of Taunton is lighted by their system, and suggest that we be authorised to send a deputation to inspect the same." (The following footnotes were appended:—"*i.e.*, 7½ per cent. on the capital sunk in the plant and machinery;" "*i.e.*, 5 per cent. on the paid-up capital.")

Mr. SLY reminded the Court that they rejected both the original suggestions of the Brush Company, and instructed their officers to draw up specifications for the lighting of the City. The Streets Committee divided the district into three sections—West, Central, and East. Two other companies proposed alterations in their specification, which the Court refused to agree to, and they accepted the offer of the Brush Company to light the Central district, because that Company adhered to the specification as the basis of an agreement. Afterwards the Court agreed to certain modifications, and now the Brush Company asked them to sanction further alterations. If they gave this Company the right of exclusive private supply for 21 years, whether the contract for public supply should be determined or not, they would not be studying the public interest, and they would be giving the Brush Company an advantage over the other two companies. The Brush Company first of all agreed to their proposals, and then, having got a certain hold upon them, they took up first one point and then another to their own advantage. He thought they might possibly get better terms under a Provisional Order. He moved that the matter be referred back to the Committee for reconsideration.

Mr. BRIDGMAN called attention to the footnote, and asked what the capital sunk in plant and machinery and the paid-up capital was likely to amount to.

Mr. CLOUDSLEY (Chairman of the Streets Committee) said they could not possibly tell. No doubt the Company would provide plant for the purpose as cheaply as possible.

Mr. BOWRING seconded the amendment. He thought to hand over the private lighting to any Company for 21 years would be a disastrous thing. They had to consider what might be the improvements in electric lighting during the next ten years.

Mr. A. A. WOOD was positively opposed to the private lighting clause, which he believed would be a gross injustice to the citizens. It was eminently advisable that they should, without delay, make a contract with some company for the supply of the electric light to the City, and he suggested that they should get rid of the word "exclusive." The Brush Company had shown great enterprise, and if they agreed to compete with other companies for the private supply of the City, the Commission would make a satisfactory bargain, and the consumers would get the electric light at a reasonable price.

Mr. BRIDGMAN said, besides the accumulated 10 per cent. allowed on the sliding scale there was now to be 7½ per cent. allowed for depreciation. The report said that this 7½ per cent. was capital sunk in plant and machinery. He assumed that the Company would require to call up at least £100,000 to carry out this work. They were entitled to have 5 per per cent. on that called up capital, which came to £5,000 a year.

Mr. PANNELL: The footnote is absolutely incorrect. It is not 5 per cent. on the paid-up capital.

Mr. CLOUDSLEY: It is a mistake.

The SOLICITOR (Mr. Baylis) afterwards explained that it was 5 per cent. on the profits available for dividend; and the report was altered accordingly.

The CHAIRMAN stated the history of the question, observing that it was most desirable that members should thoroughly understand the matter on which they were voting. Mr. Sly was wrong in saying that an absolute arrangement had been made with either of the companies. The Court had agreed upon a principle, and the solicitor had prepared a contract based on that principle. That was really as far as they had gone. It was the business of the Committee to try to tide over any difficulties which might arise. It was the public supply which they had in the first instance to direct their attention to; private users would to a large extent look after their own interests. The Company said they ought to have some consideration for wear and tear of plant and machinery, and this appeared to him a very reasonable proposal.

Mr. C. T. HARRIS described the action of the Brush Company as the most extraordinary repudiation of a deliberate agreement made with the Commission he had ever known. Were they to enter into a fresh contract which was not favourable to the Commission in one degree, but which was all in favour of the contracting Company? The proposed alterations were not on points of detail, but on points of principle. If they agreed to this they would only be able to continue the public lighting on the Brush Company's terms. They would have contracted themselves out of the Act which was designed for the benefit of consumers. The sliding scale was an entirely impracticable thing. Amongst the five companies applying to the Board of Trade for Provisional Orders were two very large and substantial companies, two of the largest in England—the London Electric Supply Corporation and the Metropolitan Electric Company.

Mr. PANNELL said the Commission considered that the two Companies referred to, notwithstanding the grand names attached to them, could not possibly be come to terms with. As far as he understood the question before the Board of Trade, it was this: If they could come to an arrangement with a company or companies for two of the districts, the Board of Trade would assist them; and, as far as they could, he took it these companies would get their agreement with them substantiated and approved by the Board of Trade. If they did not come to that agreement within a very limited period, he understood the Board of Trade would hand over all the applications now made for Provisional Orders to a Committee of the House of Commons, and they would have to go and oppose them there. He was informed on very good authority that this was the position. It did not very much matter, as long as they did not concede vital principles, what concessions they made, so long as these concessions were not more stringent than the applications for Provisional Orders. He did not think in the Provisional Order there was an arrangement for a sliding scale at all. Therefore, however trammelled their sliding scale might be, it was better than nothing. He understood it would take at least £300,000 outlay to cover the district they proposed to allot. If they desired to see the electric light introduced into the City of London they must do their best to compromise and meet the resources of these people who were going to find the money. He pointed out that a profit would actually have to be created by the Company before 5 per cent. could be set off.

Mr. Deputy SCOTT, Mr. SHAW, and Mr. DRESSER ROGERS having spoken, the amendment was negatived by 28 to 14 votes.

Mr. PELLETT moved to omit the word "exclusive," which was also defeated; and the report was agreed to.

On the motion of Mr. GRAHAM KING the deputation to Taunton was limited to ten members.

GOOD FRIDAY.

In Good Friday Week "THE ELECTRICIAN" will be published on Thursday morning (April 3), instead of on Friday (April 4).

Contributors, Correspondents, and Advertisers are requested to take note, and to forward their communications as early as possible, but not later than Tuesday night in Good Friday week.

"TELEGRAPH CLERKS' GRIEVANCES."

Under this heading there appeared in *The Times* of the 4th inst. a manifesto of formidable dimensions, setting forth the grounds of dissatisfaction which for a long time past the public have been assured through Parliament and Press is widely prevalent among the *employés* of the Postal Telegraph Service. That service is a highly valuable one to the public, and the telegraphists are a very numerous body of public servants. The combination among them which is threatened in the document above referred to is, therefore, an event of considerable moment, and one which will attract a good deal of attention apart from the character of the grievances which the combination is designed to remedy. We had the POSTMASTER-GENERAL's assurance in Parliament last Friday that no hindrance or penalty would attach to telegraphists who united for purposes

of this sort, so long as they did not presume upon their position to commit breaches of discipline which could not be tolerated in other people. Mr. RAIKES has displayed a similar leniency towards postal *employés*, who have been allowed to assemble and discuss their grievances in a manner not permitted by any of his predecessors. It may, therefore, be assumed that this movement among the telegraphists will go forward unimpeded by the officials; and that, if there is any real strength in it, there will be created a proportionate amount of pressure to enforce its demands. We say "enforce," for it is hard to see what object "an association with offices, and half-a-dozen sub-committees actively engaged," can have, unless to extort by threats what would not be yielded to argument.

Now, the public have lately been made only too familiar with associations of that kind; and whatever else may be said of them, one thing has been perfectly clear throughout all the recent strikes, namely, that the public take no account of the causes of dispute, but concern themselves with the consequences only. Probably on this fact their representative committees have presumed in drawing up the "Telegraph Clerks' Grievances." We never saw a manifesto so long containing so little. Approaching it with a predisposition to sympathise with any reasonable claims put forward by a highly intelligent and fairly well-educated body of men, we have left its perusal with feelings of an exactly opposite kind. We still retain too high an opinion of the telegraphists to believe that this document is a fair expression of their views, or a correct sample of the way in which they would be put if the men were left to themselves. The fact seems to be, that in all movements of this kind, when once their interests are handed over to a separate and practically irresponsible coterie, whose business it is to create or magnify grievances, the original complainants disappear from the scene altogether And the case of the telegraphist is apparently no exception to the rule; for both in this manifesto, and in the questions subsequently put into the mouths of Members of Parliament, there is abundance of evidence that the moving spirits either do not really understand the matter with which they are dealing, or are so inconsequential in their reasoning as not to perceive the contradictory nature of their own actions.

For example, one of their foremost grievances is that superior appointments are not open to telegraphists. Not many nights after this was printed the POSTMASTER-GENERAL was taxed with having selected certain telegraphists for superior appointments "over the heads" of their seniors. The selections, as it turned out, were on account of superior fitness. Do the memorialists suppose that advancement to those positions of postmasters and surveyors' clerks, which are so much coveted, can be made on any other grounds? Again, while complaining of stagnation of promotion, they deprecate the fact that a great number of the men at the Central Office, possessing equal qualifications and equal length of service, are in receipt of widely different pay. We know nothing as to the facts; but it is obvious that without some such inequality promotion would indeed be stagnant, for there would be nothing to promote to. In the same way "classification" is objected to; but without classification, promotion, instead of being, as it is, generally by fixed stages and according to seniority, would be ruled by selection solely, as in most private businesses, where "passing over" is common. In point of fact, directly the meaning of this much-derided "classification" becomes generally known, the more will the telegraphists be envied rather than pitied. There is only one conceivable explanation of their complaints on this point, namely, that they not only want to be at the top of their own class, but will never be content till they all get to the top of the classes above them. Apparently they are everyone fit for superior appointments, and everyone must have them, or the POSTMASTER-GENERAL shall know the reason why. Pushed to its logical outcome, almost every paragraph in the manifesto would bear the interpretation, briefly, that we are all equal, and are all equally entitled to be highly paid. The premises and conclusion both are absurd; but, unfortunately, there is no absurdity of which a trades' combination committee cannot be guilty.

Examining the manifesto as a statement of facts, we are again met by the same disregard of the most elementary precautions indispensable to the success of any appeal to a Government department. It is alleged among other questionable things that the telegraphists "never accepted" Mr. FAWCETT'S scheme. If our recollection is not greatly at fault, they profited by it considerably; and to say that they did not accept it in the sense of having rejected it is simply untrue. Further, they complain of "deduction of pay during sickness." The public will naturally think this a grievance; but when they come to see what the deduction really is, they may probably think, as we do, that this language is rather calculated to mislead. The same remark applies to the hours of duty. Telegraphists have already obtained that ideal working-day of the British artisan—with the meal times, we believe, thrown in. We learn from this memorial also that telegraphists are paid overtime *pro ratâ* on their salaries, and that somehow or other they consider this a grievance, asking in the same breath to have their hours of work reduced to seven as in some other Government departments, where, in fact, the *pro ratâ* system is unknown. These telegraphists prefer to designate themselves Government clerks—and we rather commend them for it; but in what other public department do Government clerks get paid overtime at the same rate as their salaries? There may be exceptions; but we have always supposed that the much-talked-of 10d. an hour was the rule. The telegraph clerks' modest demand is for a rate and a quarter for overtime—that is to say, wages of 48s. a week shall entitle the recipient to 1s. 3d. per hour overtime. There is only one thing to be said for such a contention—that it would tend to do away with overtime entirely; and if what they assert with reference to the mental and bodily strain of their normal duties be true, the sooner they are relieved from the additional work (and its remuneration) the better it will be for the Telegraph clerks. But here again we hesitate to accept statements which if literally true would go to prove that telegraphy is one of the most exacting and exhausting occupations known to us. If medical testimony will bear this out, there is no need for associations and sub-committees to obtain redress for one, at least, of the telegraph clerks' grievances. As for the rest they are summed up in the phrase "reasonable pay." We do not pretend to know what is reasonable pay for a telegraphist; but for the discussion of every such question on a satisfactory footing there must be reasonable people on both sides; and from the amount of unreason embodied in the manifesto now put before the public on behalf of the telegraph clerks, we are persuaded that reasonableness is not conspicuous in that quarter. We should be the last to deter them from trying by every legitimate means to obtain a better scale of pay if they can justly claim it; but we would point out to them that in this, as in all other callings, there is a limit beyond which it is impossible for the rank and file to rise, and that the reasonable course to adopt is to keep expenditure well within that limitation, neither forestalling nor counting upon those rare promotions to higher grades which must necessarily fall only to the exceptionally fortunate or the exceptionally gifted few. Men as a rule are *not* equal, and telegraphy tends rather to develope the higher qualities where there happen to be any.

OBITUARY.

JOHANN GEORG HALSKE.

The death is recorded, at Berlin, of Herr Johann Georg Halske, the co-founder and, for many years, partner of the well-known firm of Siemens and Halske. He was born at Hamburg on July 30, 1814, and went to Berlin, where he set up an engineers' shop, in 1844. Soon after he made the acquaintance of Werner Siemens, and it was in Halske's workshop that Werner Siemens, assisted by the mechanical skill of the former, was able to work out his first inventions in telegraphy so as to bring them before the public. In 1847 the two men entered into partnership, and laid the foundation of the electrical works which at the present day give employment to thousands of workmen both at Berlin and Charlottenburg, and at several branch establishments. Herr Halske left the firm in 1867, and since then has been an active member of the municipality of Berlin.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

THE THEORY OF ARMATURE REACTION IN DYNAMOS AND MOTORS.

SOME POINTS IN DYNAMO AND MOTOR DESIGN.

DISCUSSION. (Authorised Abstract.)

February 27th.

Before the commencement of the discussion proper, Mr. ESSON made a few remarks on the construction of the armature cores in the machines used as dynamos and motors, the results of which are given on slip 19 (*The Electrician*, March 21, p. 495). The Gramme and Pacinotti, he said, were built up of thin discs, whilst the Bürgin had wire cores carried by six-armed spiders. He thought the great difference between the E.M.F. of the latter when used as dynamos and motor might be due to the iron wires having been brought into electric contact by forcing the spiders in the rings and thus causing parasitic currents. He also corrected an error made in stating Mr. Ravenshaw's rule on slip 13 (*The Electrician*, March 14th, p. 475), where instead of the ampere-turns being 24 and 48 times the area of the field-magnets, 35 and 70 times the area of the armature core should be substituted. With reference to this rule, Mr. Esson said, if it was true, then by doubling the length of an armature the load might be doubled without giving rise to sparking. In his opinion the ampere-turns should remain the same. Again, Mr. Ravenshaw's rule would, when applied to similar machines, give the ampere-turns on armature proportional to the square of the radial depth of core, whereas on slip 12 (*The Electrician*, March 14th, p. 475), this was shown to be proportional to the first power of the depth.

Prof. AYRTON said he was particularly interested in Mr. ESSON'S Paper because it contained so many experimental results. Referring to Mr. Swinburne's method of treating the subject, he deprecated the use of the term "magnetic potential" where "difference of magnetic potential" was meant. He also thought Mr. Esson's term "working saturation," slip 3, § 4 (*The Electrician*, March 7th, p. 451) was not to be recommended, and that "working induction" would be much better. In his further remarks the Professor said he would confine himself chiefly to three heads, which were brought out prominently in a Paper on "Electromotors," by Prof. Perry and himself in 1883 (*The Electrician*, August 11, 1883, *et seq.*), and about which considerable difference of opinion still existed. These were—1st, the existence of magnetic lag; 2nd, the alteration of resistance of revolving armatures by self-induction; and 3rd, motor construction for minimum weight. As regards magnetic lag, this, he said, had often been denied; but quite recently Prof. Ewing had shown that such lag did occur, amounting in some cases to several minutes. With reference to the increase of resistance of revolving armatures due to self-induction, he thought some misunderstanding existed; for Mr. Swinburne in his Paper says that "power cannot be lost by self-induction." In their original Paper Prof. Perry and himself had given a formula for calculating this loss when the brushes were placed at the neutral position, and this they confirmed experimentally. When, however, this condition is not fulfilled a modification is necessary. If the brushes could be placed at an absolutely non-sparking position the resistance of the armature would not be increased by rotation, for then a section leaves the brush and is thrown into circuit with the proper current in it, and hence no further E.M.F. is needed to bring the current up to its proper value. In fact, the energy used in starting the current is supplied by the belt whilst the coil is short-circuited. He also said that in a dynamo with sparkless lead, the coils between the neutral lines and the brushes acted as motor coils and assisted the rotation of the armature, whereas in a motor they act as dynamo coils and oppose the rotation. Before passing to the third heading, reference was made to some remarks of Mr. Esson in the discussion on Mr. A. T. Snell's Paper of "Design of Motors," read before the City Guilds Old Students' Association last year. Mr. Esson then said that the chief use of the series winding in compounded Manchester dynamos was to counteract the demagnetising action of the armature. To test this, experiments had been made on such a machine, and it was found that out of 10,560 ampere-turns required at full load, 2,660 were required to compensate for back induction, and 2,100 for loss due to resistance of armature. Commenting on "The Best Relation of Iron to Copper in Armatures" (slip 17) (*The Electrician*, March 21, p. 494), Prof. Ayrton thought it a mistake to assume constant induction in the armature, for an increase of copper would mean greater excitation. Taking the excitation as fixed, Prof. Perry and himself had shown (*Proc.* Phys. Soc., Vol. IX., p. 220) that maximum output was obtained when the magnetic resistance of the space occupied by copper was equal to that of the rest of the circuit. As regards the question whether motors should or should not be made different from dynamos, the speaker said that in an Immisch series motor run as a dynamo and as motor at the same speed and current, the E.M.F. (neglecting self-induction) was 14 per cent. greater as a motor, and when the maximum possible effect of self-induction was allowed, a difference of 10 per cent. still remained. This had since been confirmed by measuring the induction in the field-magnets, both when a current was sent through the magnet coils alone, and then through both magnets and armature, the latter revolving at 1,400 revolutions as a motor. In the latter case the induction was 5 per cent. greater than in the former. Experiments on the characteristics of a magneto Gramme used as a generator and as a motor with equal lead and trail, show that as a dynamo the curve falls as in Fig. 15 (*The Electrician*, March 7, p. 451) of Mr. Esson's Paper; whereas, as a motor, the curve rises with increase of current. On trying the same experiments with a separately excited A Gramme, the E.M.F. as a motor always increases with the current through the armature, whatever the strength of exciting current used; but as a generator the E.M.F. always decreased, and, with a weak field, became negative when the armature current increased. In conclusion, Prof. Ayrton contended that the above experiments, as well as those of Mr. Esson on the Bürgin machine, proved conclusively that a relatively powerful armature strengthens the field of a motor and weakens that of a dynamo.

Mr. RAVENSHAW said that, apart from their own merits, Mr. Swinburne's and Mr. Esson's Papers would be most useful in promoting discussion on the causes of sparking. As regards Mr. Esson's expression for the ampere-turns which may be carried on an armature, he could not say that it held good in practice. He himself had experimented a good deal on the subject, and the results seemed to point to the fact that, for all sizes and shapes of well-designed machines, their behaviour at the brushes would be very similar when the ratio between the ampere-turns and the total induction in the armature was the same. This he gave not as a law, but as a result of his own experience. This experience, however, did not agree with that of Mr. Esson. One machine made for 4,000 watts, on which he had made many experiments, had a very small distance between the pole-pieces and armature core, and the pole-pieces were rather close together. After testing it under these conditions up to 6,000 or 7,000 watts, he tried it with the field bored much larger, and also with the poles cut off until they embraced an angle of 90deg. Under all these conditions the maximum ampere-turns it would carry without sparking appeared to be the same, the armature induction being kept constant. This machine was afterwards wound with a drum armature, and he had built two other types of machines with the same area of armature core, both of which carried the same ampere-turns. The above table shows Mr. Esson's coefficient for these three machines. According to Mr. Esson, No. 4 should have carried double the ampere-turns on No. 6, but as a matter of fact No. 6 sparked decidedly the least. No. 8 was built when copper was very expensive, and was in all *other* respects the same as No. 7, excepting that it had a large armature, large polar surface, and a very short air-space. Both machines were sparkless, but began to spark at about 50 per cent. above full load. Nos. 1, 2, and 3, were of entirely different design, agreeing only in the area of armature core. They all behaved in exactly the same way at the brushes when working with the same number of ampere turns on the armature. All the eight machines sparked a good deal with 50 per cent. more load than that given in the table. Mr. Esson had said that if the length of the armature were increased, the ampere turns must be kept constant. In reply to this Mr. Ravenshaw said he built all his machines in sets of three, the only difference between the largest and the smallest of each set being in the length of the armature and magnet cores, and the ampere-turns on the armature were increased in the same proportion. In Gramme armatures the output was limited by sparking, but with drums it was limited by heating, for the ampere-turns which could be carried by the latter were at least double those of the former. Speaking of magnetic leakage, Mr. Ravenshaw said most engineers seemed to think it impossible to calculate it with certainty; but this was erroneous, for he had been in the habit of calculating the leakage from the drawings for some years past, and always obtained accurate results. This was important, as he found that the leakage may be as high as 45 per cent., and as low as 20 per cent.

	Dynamo.	Kilowatts.	Mr. Esson's coefficient.	Ampere-turns. Armature core area.	Armature.
1	4-pole	16	40,000	31	Gramme
2	Under type	16	50,000	32·5	Gramme
3	Gramme field	16	70,000	28·5	Gramme
4	Under type	6·5	36,000	72	Drum
5	Over type	6·5	62,000	67	Drum
6	Over type	6·5	73,000	64	Drum
7	Over type	46	151,000	61	Drum
8	Over type	46	220,000	60	Drum

Mr. KAPP stated that the two Papers under discussion would form very important landmarks in the development of the dynamo, and said the subjects treated in them had been brought into prominence by the use of large machines. According to Mr. Swinburne, the limiting diameter of armatures in two-pole machines was about 40 centimetres, but he (Mr. Kapp) had, by increasing the dimensions of all the parts proportionately, made dynamos with 50 cm. armatures, and others had gone still higher. Referring to formula 2 in Mr. Swinburne's Paper (*The Electrician*, February 14th, p. 374), he asked whether the coefficient M was correct, for, as given, the length of the armature was not taken into account. His own experience gave coefficients varying from 0·12 to 0·18, instead of from 0·08 to 0·085. He also found that the magnetic leakage resistance in English measure for two-pole dynamos of the upright type was expressed by the formula $\frac{680}{\sqrt{ld}}$, and for the inverted type by $\frac{460}{\sqrt{ld}}$, where l and d are the length and diameter of the armature in inches. As regards reversing pole-pieces, he said that they were brought out about about five years ago by Mather. Coming to Mr. Esson's Paper, Mr. Kapp wished to add one device for equalising the field in single-magnet machines, which had been omitted from the interesting collection on slips 4 and 5. This device consists in making the upper horns *b*, Fig. 7 (*The Electrician*, February 28th, p. 425), rather longer than the lower ones. As regards the ratio of armature to field section dealt with on slips 6 and 7 (*The Electrician*, March 7th), he thought the remarks there made were only applicable to badly designed machines, for in good dynamos there was no room for such radical changes. The agreement of Mr. Esson's coefficients in Table II. (*The Electrician*, March 14th, p. 475), he said, was rather surprising at first sight, but on examining the formula it may be seen to be equivalent to saying that the maximum ampere-turns on an armature may be proportional to the ampere-turns on the field-magnet required to produce a given induction in the armature—a not unnatural conclusion. His own opinion was that both Mr. Esson and Mr. Ravenshaw loaded their machines too heavily. As a rough rule he found that the expression ampere-turns on armature $=1{,}000\ (d-5)$, where d is the diameter in inches, agreed very well with his practice. He cordially endorsed Mr. Esson's remarks on the small rise of temperature allowed by the Admiralty, for a rise of 11° C. meant enormous machines for their output. On the other hand, he usually allowed more cooling surface than Mr. Esson, his rule being 1·5 and 2·5 square inches per watt wasted in armature and magnets respectively. Referring to the relation between size and output, Mr. Kapp thought the exponent 2½ given by Mr. Esson was rather low; for, from actual tests on machines with armatures varying from 7in. to 13in. in diameter, he found that for Gramme-winding the output varied from d^{3} to $d^{3\cdot7}$, and for drums from $d^{3\cdot3}$ to $d^{3\cdot9}$.

Mr. FARQUHARSON said he thought the Admiralty rule for limiting rise of temperature had been misunderstood, and in Mr. Esson's Paper it was wrongly stated, for the rise permitted was 30° F. and not 11° C. The method of testing adopted by the Admiralty was to take the temperature outside the insulation immediately the machine was stopped. This temperature was by no means the same as that within the conductor, for he had known the outside temperature to rise for 20 minutes after the machine was topped.

Keeping this fact in view, together with the long continuous runs (sometimes amounting to 24 days and nights) to which ship-lighting dynamos may be subjected, he thought the Admiralty were justified in fixing the limiting temperature low enough to be safe for all machines. As a proof that the rule was not impracticable, he mentioned that all of 12 machines already delivered this year were well within the limit allowed.

Mr. A. T. SNELL, speaking of machines run as dynamos and as motors, said he always found it possible to get a greater output at a given speed when running as a motor, and that the trail as a motor was always less than the lead as a dynamo. In fact, with motors used for tramcars they worked without lead, and run in either direction with the same pair of brushes. Another point in which motors differed from dynamos was the possibility of using very thick brushes with advantage in the former, whereas in the latter such a proceeding proved disastrous. These differences seemed to him to show that the magnetic distributions in generators and motors are not the same, and that in dynamos the field was more straggling and subject to greater distortion. Referring to Mr. Esson's formula for the loading of armatures Mr. Snell said he had tested it on machines with which he was acquainted, and although he found a certain agreement, this was by no means so close as the numbers given in the Paper. He had himself been in the habit of using the formula

$$\text{Electrical horse-power} = l\ d^2\ n\ \text{K},$$

where l and d are the length and diameter of the armature, n the speed, and K a constant; and this gave close approximations where the armatures have the same proportions (*The Electrician*, March 14, p. 463). Alluding to rise of temperature in large machines after long runs, he mentioned that in some machines designed to work between 50 and 100 horse-power this amounted to 50 deg. Fahr., the temperature being taken on the wire on the inside of the cylinder armatures.

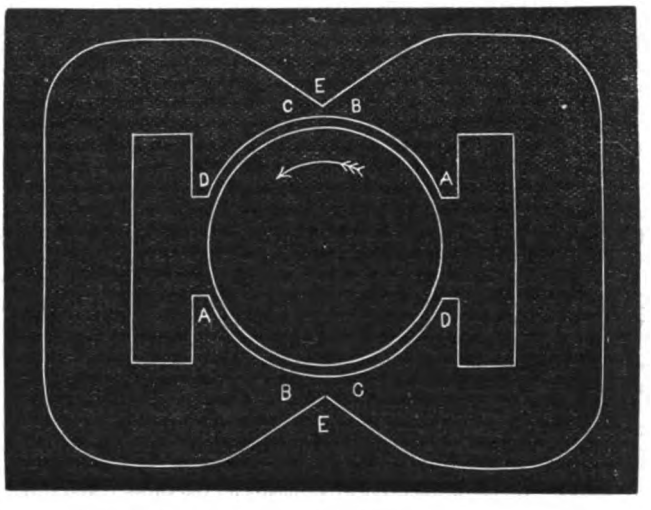
The discussion was then adjourned to March 13th.

March 13.

Prof. AYRTON exhibited curves, representing results of experiments on the Gramme magneto and Gramme dynamo when run as motors and generators, which he described on February 27th. Another curve showed similar results obtained with a Manchester dynamo separately excited with half its normal current. In this machine, run as a generator with a lead of 11deg., the E.M.F. decreases with increase of current in the armature, whereas when run as a motor, with a trail of 11 deg., the E.M.F. rises under the same conditions. From these observations he concluded that Mr. Swinburne and Mr. Esson were wrong in saying that the back E.M.F. in a motor could not be greater than the forward E.M.F. in a dynamo working under the same conditions as to speed and current. The secret of obtaining this increased E.M.F. in motors was, he believed, the employment of a relatively powerful armature.

Mr. WILLANS, referring to Mr. Esson's remarks on slip 4 (*The Electrician*, February 28th, p. 425), relating to the magnetic pull on armatures of single-magnet machines, said the inverted type there described (Fig. 5) was the worst that could be adopted; for, by employing those of the upright type (Fig. 4), the magnetic pull could be caused to support the weight of the armature, and the supposed defect converted into a distinct advantage. Speaking of the Admiralty temperature limit criticised by Mr. Esson and Mr. Kapp, he said that in testing the combined efficiency of engines and direct-driven dynamos, they had, with machines that run cool, obtained 84 or 85 per cent. of the indicated horse-power available at the dynamo terminals. On the other hand, machines that get hot never yielded more than 70 per cent. Whilst agreeing with the Admiralty that the rise of temperature allowable should be small, he objected to the method of taking the temperature; this method he characterised as being more a test of the heat conductivity of the insulation and the thermometer than of the temperature of the machine.

Prof. FORBES said both authors had touched upon very important points which had not been previously discussed in public. As regards Mr. Swinburne's Paper, he said non-mathematical readers should not accept unreservedly all the conclusions there arrived at, for some of them are admittedly based on approximations and assumptions which are not always fulfilled in practice. Nevertheless, he considered the treatment a step in the right direction. He could not accept Mr. Swinburne's statement that self-induction *prevents* waste of power, for all sparking is due to self-induction, and consequently it *causes* a waste of power. Another point about which he had grave doubts was the efficiency of the method of throttling cross-induction shown in Figs. 3 and 4 (*The Electrician*, February 14, p. 375).



His own (Prof. Forbes') opinion was, that such methods would tend to concentrate the lines about B and D (*see* Figure), whilst the field at A and C would be relatively weak. He also thought that, by partly filling up the space at E, a greater induction through the armature would be obtained. Referring to reversing pole-pieces, described on slips 8 and 9 (*The Electrician*, February 21, p. 400), he thought them ingenious, but open to considerable objection, and believed other and better means of preventing sparking would be devised. Coming to Mr. Esson's Paper, he said the remarks on slip 2 (*The Electrician*, February 28th, p. 424) respecting the utility and accuracy of calculating the waste field were directly opposed to his own opinion on the subject, and also to the experience of Mr. Ravenshaw. This point he thought gave a good instance of how some self-designated "practical men" object to spend the few hours necessary to calculate the waste field, and prefer spending a month's labour in making a machine, with all its attendant expense, in order to obtain experimentally results which could have been readily derived by calculation. He congratulated Mr. Esson on the many experimental results given in his Paper, and on the valuable and interesting way in which he had treated the subject of loss by hysteresis, illustrated by Fig. 14 (*The Electrician*, March 7th, p. 450), and the distortion of the field produced by the armature current. His own experience with non commutating dynamos had brought the latter phenomenon prominently before him, for he had found the E.M.F. at full load to be about half its value at no load. This he attributed to the fact that a given demagnetising force produces a much greater change of induction than that produced by an equal magnetising force when the iron is not saturated. Referring to the loads carried by armatures, slip 10 (*The Electrician*, March 14th, p. 475), he considered that the limit should not be fixed by sparking, but rather by questions of heating and efficiency. Armatures designed on the latter line should then be examined by the light of Mr. Esson's formula, and if they do not satisfy, the non-sparking condition must be modified accordingly.

Mr. MORDEY regretted that Mr. Swinburne's Paper was not printed so fully as it was read. He did not agree with Prof. Forbes as to the result of reducing cross-induction by the methods shown in Figs. 3 and 4 (*The Electrician*, February 14, p, 375) of Mr. Swinburne's Paper; in fact, he considered the plan quite natural, and it was very effective in well-designed machines. He thought that subsidiary or reversing pole-pieces would not

Digitized by Google

be practical, and that sparking is generally due to overloading; a better plan of preventing sparking would be to utilise the additional length of armature which the pole-pieces require, for lengthening the main core, thereby reducing overloading.

Mr. SWINBURNE here pointed out that the devices were not merely to prevent sparking but to reduce the back turns, thus diminishing or rendering unnecessary the series windings on compound machines for constant E.M.F.

Mr. MORDEY (continuing) referred to "small air-space dynamos," slip 12, (*The Electrician*, February 21, p. 401), and said Mr. Swinburne was once a great advocate of such machines, as well as of "large-output dynamos." However, as far as he was aware, no great progress had been made with either variety, for makers seem to have come back to machines having moderate air-spaces and of moderate output. Speaking of "high-tension constant-current dynamos," he said many difficulties were met with in smooth commutator machines under varying load. The Brush machine had been shunt wound for arc lighting, and many machines were so acting, but the plan was only suitable for special cases. For light loads it was unsuitable, and, on the whole, the series method was best. As to the heating of the pole-pieces, he pointed out that there were two causes of unequal heating—one was the action of magnetic tufts, which always heated the same pole, the trailing horn; the other, and more important, was the action set up by the current in the armature coils. The pole heated most by this latter cause was behind the brush in a generator, but in front of it in a motor. Thus, if a Brush machine is run with the brushes in the same place as a motor as when used as a dynamo, as may be done by reversing the field, the same pole-piece will heat in both cases; but in a motor the heat will be less, because the two causes of heating referred to are not acting on the same pole. In a dynamo the effects are added, in a motor they are subtracted. In discussing methods of measuring temperature of machines, he said this was sometimes done by measuring the resistance of the armature when hot; but this was not to be relied upon, for owing to expansion and consequent change of contact resistance at the soldered joints, the resistance hot might be less than when cold. Referring to Prof. Ayrton's remarks on the construction of "light-weight motors," Mr. Mordey said such machines were like "large-output dynamos" in not being successful in practice. He then read abstracts from Profs. Ayrton and Perry's Paper on "Electromotors, &c.," which in his opinion had retarded rather than advanced motor design. He contended that both in dynamos and motors an armature which produces no appreciable field is the best. As regards "magnetic lag," he said that any such ag of practical importance would prevent E.M.F. being proportional to speed. Experiments on a Victoria Brush machine showed that from 200 to 1,200 revolutions per minute the E.M.F. curve was a straight line, in spite of the eddy currents, which increase as the square of the speed.

Prof. AYRTON here remarked that Dr. Thompson, who agrees with Mr. Mordey as to the non-resistance of magnetic lag, entirely disagrees with him on the question of E.M.F. being proportional to speed.

Mr. MORDEY, in reply, said he was not answerable for Dr. Thompson's statements, but he was quite sure that in well-made machines he had tested the E.M.F. was exactly proportional to speed.

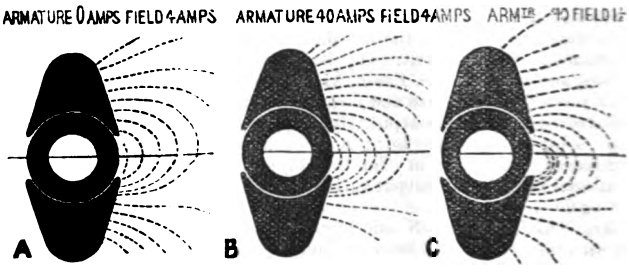
Mr. W. B. SAYERS questioned the accuracy of Mr. Swinburne's view of the action of coils short circuited by the brushes given on slip 11 (*The Electrician*, Feb. 21) and thought the various statements were not consistent. The real effect was a diminution of the induction in dynamos and an increase in motors. He had made many experiments on the subject, and invariably found that for a given speed and current the E.M.F. of a machine run as a motor was greater than that when used as a dynamo, and the same thing is shown, with one solitary exception, in Table IV. (*The Electrician*, March 21, p. 495) of Mr. Esson's Paper. Laminating the cores has the effect of decreasing the divergence. One serious cause of sparking which had not been referred to in either Paper was the want of accuracy in making all the sections and commutator bars exactly alike, and spacing them with rigorous exactness round the armature. In his opinion nothing short of the accuracy obtained by engineers in cutting wheels would effectually overcome sparking. Neglect of such precaution causes variation in the non-sparking position, the result of which may sometimes be seen in some segments being marked whilst the others remain perfect.

Mr. CROMPTON said he wished to bring forward a few novelties not mentioned in either of the valuable Papers under discussion; for although these Papers deal with many interesting and important points in dynamo design, they do not say how the best machines of the day are being made. Several firms, notably, Messrs. Siemens, he said, were turning out dynamos having efficiencies undreamt of several years ago. The results mentioned by Mr. Willans, for example, of a combined engine and dynamo efficiency of 84 or 85 per cent., showed that the commercial efficiency of the dynamo must be quite 93 per cent. The cause of the high figure, he believed, was to be found in the much-abused Admiralty specification, for all firms anxious to secure contracts had been obliged to devise means for reducing the rise of temperature, the result of which was greatly increased efficiency. In making large machines difficulties presented themselves which were unimportant in small dynamos; for example, as pointed out in Mr. Swinburne's Paper, the magnetic leakage across the internal cavity of Gramme armatures becomes serious. On the whole, he was inclined to agree with Mr. Swinburne's remarks on the disadvantages of Gramme as compared with drum armatures. Some doubt, he said, still exists as to the necessity of insulating the driving bands of drum armatures from the shaft; in his opinion it was not necessary. The question as to what material should be used for transmitting the driving strain from the shaft to the armature required careful consideration; he himself found aluminium-bronze and delta metal fairly satisfactory, for they combine good mechanical strength with high electrical resistance. Another point requiring particular attention was the subdivision of the armature conductors in machines for large currents. The heating of the conductors in "bar armatures" due to Foucault currents may be considerable; but by subdividing the bars into sections, and twisting them through half a turn, he had succeeded in largely reducing this effect, to about half its former value. A further improvement consists of forming the conductors from a great number of wires twisted together, and compressed into a trapezoidal form of the proper shape for the winding. In illustration of the various methods of subdivision above referred to, Mr. Crompton exhibited specimens of conductors made by his firm. Speaking of the arrangement of the radiating surfaces or armatures, he said the question, does it pay to cover all the surface of the core with copper, or to leave spaces between the sections to give increased surface was still open to discussion.. Referring to Mr. Mordey's statement about the lessened resistance of hot armatures, he said he had never observed such an effect, and thought the joints in machines exhibiting such peculiarities must have been defective. In conclusion, Mr. Crompton replied to Mr. Esson's remarks on slip 12 respecting dynamo No. 4, Table II. (*The Electrician*, March 14, p. 475), by saying that this was the first machine in which the design had been influenced by the idea of magnetic resistance, and he was glad to see that its armature was the father of all modern ones of the Gramme type. In support of this he pointed out that the ratio of radial depth to diameter was 1 to 5, a proportion now almost universally adopted.

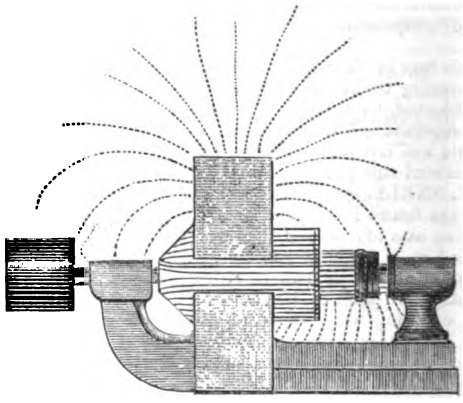
The discussion was then adjourned to the 20th inst.

MARCH 20.

Mr. A. P. TROTTER disagreed with Mr. Esson's statement on slip 2 (*The Electrician*, February 28th, page 424) as to the inutility of and the difficulties attending calculations of the stray field, and said that since Prof. Forbes gave his three Lemmas in 1886, the work has been comparatively simple, and constituted part of the drawing-office routine at Halifax. Speaking of differences in the quality of iron, he said forged bars could be depended on, but charcoal iron was not so reliable. Any doubt as to the behaviour of iron, in his opinion, renders it all the more necessary to calculate the waste field, so that only one unknown factor may be present.



Stray-Field Diagrams.



Stray-Field Diagram D.

This predetermination is most important when any departure from ordinary designs is made, for in such cases one cannot be guided by previous experiment. As an instance of the accuracy attainable in these calculations, he said that in Messrs. Goolden and Co's. M type dynamo, where the leakage amounts to 60 per cent., Mr. Ravenshaw predicted this to within 1 per cent. Mr. Trotter also exhibited some interesting diagrams plotted by a novel method on the machine itself, which showed the directions of the waste field under various conditions of armature and field excitation; on one of these the distorting effect of a large armature current could be easily seen. From such diagrams, A, B, C, D, combined with Prof. Forbes' formulæ, the speaker was of opinion a line could be determined, in terms of whose length the magnetic resistance between any two parts considered may be stated.

Mr. VIGNOLES confirmed Mr. Trotter's remarks about the calculations of waste field by Mr. Ravenshaw. He also pointed out that Mr. Esson used the word "saturation" in various senses, and he thought it desirable that a distinct meaning be given to the word by definition.

Mr. S. JOYCE, speaking of Mr. Esson's rule for rise of temperature, said such rules could only give the temperature at the surface, and not that of the interior, which was probably much greater. As the difference in temperature between the inside and outside of the winding varies as the square of the depth, this difference may become excessive in large machines. The expression for the difference on the assumption that the inside and outside sur-

Digitized by Google

face are parallel planes was given as $\frac{h D^2}{2K}$, where h = C.-G.-S. heat units generated per cubic centimetre, D = depth of winding, and K its thermal conductivity. For cylindrical surfaces of ordinary dimensions, the difference is about 3 per cent. less. The quantity K may be calculated from the equation $K = \frac{Z d}{Z\delta}$, where Z is the thermal conductivity of the insulating material, d the diameter of the covered wire, and δ the radial depth of insulation. The speaker said the value of Z given for cotton by Prof. Everett was ·00201, by Prof. Forbes ·00003; but he himself found it ten times the latter, viz., ·0003. His own experiments on "emissivity" of varnished cotton gave the number ·0005, whereas Macfarlane's result for blackened copper was ·0003. He had also found that by leaving about 10 per cent. of armature cores exposed, the difference of temperature between the inside and outside of the winding was reduced to a quarter that which exists when the whole surface is covered with wire.

Mr. J. D. F. ANDREWS said the specimens of armature winding exhibited by Mr. Crompton were very interesting, but thought the heating difficulty could be got over in a simpler way. In one dynamo he had constructed with bars ⅜in. by ⅜in. the heating was immense when running at no load. On cutting away the pole-pieces tangential with the armature the rise of temperature was 100° Fahr., and by putting the bars on edge this was reduced to 30 deg. After rounding off the top corners of the bars there was no heating.

Mr. STUART A. RUSSELL, referring to Mr. Esson's curve for maximum output (Fig. 21) (*The Electrician*, March 21, p. 495), said he believed this was obtained on the assumption that the depth of winding inside the armature was equal to the depth outside. If the difference between these depths be taken into account, then in ordinary cylinder armatures, instead of the core being about four times the depth of the winding, it becomes 5¼ times. As regards size and output the speaker said he had found the rule—total induction $\propto$ (watts per revolution)$^{\frac{3}{4}}$—very convenient, and that it nearly agreed with that given by Mr. Snell. Referring to the difficulty in compounding slow-speed machines, Mr. Russell said one cause arose from the want of proportionality between the additional ampere-turns on the magnets and the back ampere-turns on the armature. In the former they are proportional to the current simply, whilst in the latter they are proportional to the current multiplied by the angle of lead. Hence, if the compensating turns are made right for full load, then the middle of the curve will be too high. Concerning the design of motors, the speaker said he agreed with the authors of the Papers, but the startling nature of the curves shown by Prof. Ayrton had led him to make experiments on the subject. In these a double horse-shoe Gramme machine was used with the magnets, and armature currents decreased and increased 40 per cent. respectively, so as to obtain a relatively powerful armature. In addition to taking volts and amperes, the field was measured by the ballistic method. The first set of experiments was made with brushes of the ordinary thickness (1¼ segments). The results showed that with no lead V – C R as a motor was about 8 per cent. greater than V + C R as a generator, whilst with lead and trail of 18 deg. the difference was 4 per cent. This difference, he believes, is accounted for by self-induction, for there was very little change in the field-induction. In a second set of experiments two brushes in parallel arranged so as to short-circuit four sections, were used; the difference between V – C R and V + C R amounted to about 75 per cent. of the mean, but it was also noticed that the change in the field only amounted to about 30 per cent., and that V – C R as a motor was greater than the E.M.F. corresponding to the induction used. From these observations Mr. Russell concludes that the E.M.F. of a motor may be made greater than that of a dynamo by short-circuiting a number of sections, thereby increasing the armature induction; but that no advantage is gained, because the result is just the same whether the greater induction is produced by field-magnet windings or by coils short-circuited by the armature brushes. His experience with motors having thick brushes did not agree with Mr. Snell's, for in tramcar work he (the speaker) got the best results with brushes of ordinary thickness.

Mr. WYLES said no doubt need exist as to the possibility of making smooth commutator machines for high voltages, and that the difficulties experienced arose from the great differences in the insulation of similar machines. The insulation of some may be excellent, whereas that of others wound with equal care is comparatively bad. These differences are met with in machines of E.M.F.'s as low as 200 volts.

Mr. GEIPEL asked whether cross induction could not be reduced by cutting the pole-pieces in Fig. 3 of Mr. Swinburne's Paper (*see* diagram in the discussion of March 13) in two parts at E E, and by laminating the magnets in a direction perpendicular to that of the cross lines. Referring to Mr. Eson's temperature limit of 75° C., he inquired whether any modification would be made for machines intended for tropical climates.

Dr. S. P. THOMPSON, in a communication read by Mr. KAPP, said a good approximation to the back ampere-turns was got by multiplying the number of conductors between the pole corners by half the armature current, and that he agreed with Mr. Swinburne as to the usual position of the brushes. He complained of Mr. Swinburne's use of "ergs" in measuring magnetic potential, and asked why in naming the pole corners he had reversed the ordinary usage. He also inquired why Mr. Esson takes the load carried by armatures as proportional to the depth of armature core. Speaking of "leakage coefficients," he pointed out that this is not constant even for machines of the same type, but is less for the larger machines. Referring to the statement by Mr. Esson that the induction in large armatures should be less than in small ones, Prof. Thompson asked whether this was true both of disc and wire cores. As regards smooth commutator machines for high volts, he said Messrs. Paterson and Cooper had made such machines successfully for some time, and that in Ball's so-called "unipolar dynamo" was an instance of a smooth commutator machine working 80 arcs in series.

Mr. MACWHIRTER objected to Mr. Swinburne's use of the symbol Ω for magnetic potential, for this was the recognised symbol for megohm. He also said that some system of symbols was greatly needed, and suggested that the Nomenclature Committee appointed by the Society some five years ago should present an interim report. Speaking of the magnetic pull on armatures of single-magnet machines, he said his firm found the method of placing the armature eccentrically very effective. Their motors were always made on the same lines as dynamos, for they found that machines with light fields always sparked.

The PRESIDENT expressed his great appreciation of both Papers under discussion; but, owing to the lateness of the hour, would only criticise a few points in Mr. Swinburne's. The rule given for lead of brushes seemed to him hardly correct, for in machines with which he was acquainted the lead was always less than half the angle between the pole corners. There were two points to which he wished to direct Mr. Swinburne's attention, viz., the effect of having a great or a smaller number of commutator bars, and of thick or thin brushes. Speaking of the term "magnetic resistance," he said there were two reasons why he did not use it; first, the generally accepted idea of *resistance* was that (*flux*)^2 × *resistance* was a rate of doing work; so-called "magnetic resistance" did not satisfy this condition; secondly, "coefficients of resistance" are generally constants, and express properties of the material or medium. "Magnetic resistance," however, is by no means constant, and he thought its use open to the same objections as "resistance of an electric arc," an expression which was very misleading.

Mr. SWINBURNE, in reply, said the main subject of his Paper had not been discussed. Its object was to show how to obtain an expression for the lead of the brushes in terms of the polar angle, and thus determine the back induction before the machine was made. This being of much greater importance in regard to large machines, the greater part of his Paper referred to such machines; but, unfortunately, many of the speakers assumed it applicable to small machines, and discussed it accordingly. Prof. Ayrton, he said, had accused him of using "magnetic potential" where "difference of magnetic potential" was meant. This he denied, and pointed out that he had been careful to speak of difference of magnetic potential. Referring to "magnetic lag," he said the "time lag" discovered by Prof. Ewing had no connection with the once supposed lag to which the lead of the brushes was wrongly attributed. As regards the results of experiments on machines run as generators and motors by Prof. Ayrton, he pointed out that in those experiments where the E.M.F. became negative with a large armature current, the generator became a motor, and the brushes were then in the wrong position. He also contended that, in all cases where the E.M.F. of a motor increased with increase of armature current, the brushes were not in the proper position. He believed Mr. Esson's results on the Bürgin machine were due to the same cause; for in this machine, unless made specially as a motor, the brushes could not be put back far enough to run sparklessly. Probably Mr. Esson had been misled by not being aware that the commutator connections are skewed. Replying to the criticisms on his use of "ergs" in measuring magnetic potential, he said Sir W. Thomson was the first to introduce it, and as it had been used by Maxwell and others, he thought he might use it too. His objections to "magnetic resistance" are—1st. That the term has no definite meaning; 2nd. that the analogy whence it is derived is wrong; and 3rd, if used, it is liable to lead to error, as has already been the case with regard to transformers. Magnetism, he said, was analogous to electrostatics, and permeability to specific inductive capacity, not to conductivity, as the advocates of magnetic resistance would have us suppose. Referring to Mr. Kapp's remarks on enlarging dynamos to scale, he said that the impossibility of doing so successfully had been pointed out seven years ago by Dr. Hopkinson, who about that time got three times the output at present obtained by Mr. Kapp and others from machines of the same weight. In his opinion four-pole drum machines would be used in the future for large power outputs. Speaking of the Admiralty, temperature test Mr. Swinburne said it was comparatively useless, for it failed to pick out the best machines. To do this the temperature of the conductors should be ascertained, and this could be done by taking the resistance of the armature in spite of Mr. Mordey's bad joints. He was sorry to learn that Mr. Mordey had not been able to make a shunt brush machine work successfully, for he himself had done so, and the inventor of the machine approved of the arrangement. As regards the position of the brushes relative to the pole corners he pointed out that Dr. Thompson's observations agreed with his own, and not with those of the President. In answer to the President's inquiry why he did not integrate to infinity, he said the integration had only been given as a rough approximation near enough the truth to show that a comparatively weak field is required to reverse the current in the armature sections of direct-current machines. If alternating machines were under consideration the treatment of the integration would be much more important.

Mr. ESSON, in his reply, said Mr. Kapp's method of overcoming side pull had the disadvantage of not allowing the coils to be slipped over the poles, and that even if adopted the distribution of the field was not the same near the top brushes as near the bottom ones; the arrangement in Fig. 9 (*The Electrician*, February 28, p. 426) gave a much more uniform field. He could not understand how Mr. Kapp saw any "dodge" in designing armatures to give large outputs, for the magnets were designed in accordance with the armatures with which they had to work. Neither could he understand Mr. Ravenshaw's remarks about the loading of armatures. In his opinion the machines of a set could not be all in the same condition as regards balance of field, and he thought all Mr. Ravenshaw's dynamos were underloaded. He was glad to see that Prof. Ayrton's remarks respecting the number of ampere-turns required for compounding agreed with his own statement on the subject. Speaking of the Admiralty test, he said the method of making the test was to heat the thermometer 30° Fah. above the surrounding air before applying it to the

Digitized by Google

armature, and then noting its rate of rise or fall when so applied. Machines giving a rise of 40 deg. were accepted subject to a fine. He was now of opinion that the rise allowed by the Admiralty was quite enough for machines which had to work in hot engine-rooms. Referring to Mr. Crompton's armature conductors, he said he had used stranded wire for the same purpose ; but the section of his subdivided conductor was round, and not made rectangular, as in Mr. Crompton's. He would have been glad to learn something about the collection of large currents, for this seemed to be one of the most difficult problems at present. On the subject of motor construction, Mr. Esson said Prof. Ayrton's curves showed that it was difficult to prove either point conclusively ; however, he thought he could see where Profs. Ayrton and Perry had been led into error. In their Paper on Electromotors, &c., the output of a machine is given as

$$W \propto (L\,l \cos \alpha + l^2 \sin \alpha),$$

where L and l are the weights of the magnet and armature respectively, and α the angle of lead. In order that this may be a maximum for a dynamo (where the negative sign is to be taken), L must be large compared with l, but in dealing with motors, the Professors said the + sign should be used, and this led to the large armature view. Mr. Esson, however, contended that the negative sign is the one to be taken for both dynamos and motors. The positive sign, he said, leads to bad machines, which always spark.

APPENDIX.

The following are copies of the letters respecting the "Wood" and "Sperry" dynamos referred to by Mr. Esson in his Paper.

W. B. Esson, Esq., London, England.

DEAR SIR,—In reply to your letter of October 21st, requesting data of machines made by this company, I send you the following :—Difference of potentials at terminals of machine, 2,640 volts ; current, 9·6 amperes ; revolutions per minute, 875 ; sections in commutator, 120 ; convolutions per section of armature, 72 ; cross section of iron in armature ring, 14 square inches. Pole-pieces are bored concentrically with the armature ; sparking at the brushes is eliminated by the use of an extra brush connected to collecting brush, with a separation or commutator of from five to ten sections, depending on the load, or, in other words, a counter E.M.F. to reduce spark. I must apologise to you for the delay in answering your letter, and hope that I may be in time for you to make use of data as intended.—I am, yours truly, CHARLES J. BOGUE,

The New American Electrical Arc Light Company.

New York, Dec. 2, 1889.

Mr. W. B. Esson, West Hackney, N.E., London.

DEAR SIR,—Yours of October 21st at hand. Am pleased to notice contents, and in reply would say that the matter of regulation by shifting the brushes I have gone into as exhaustively, perhaps, as anyone in this country. I have had unlimited capital at my disposal, and have made an exhaustive series of experiments, and can say from knowledge that it depends for its success almost solely upon what we know as the balance between the armature and field. This might more properly be termed the preponderance of the induction of the field over that of the armature. . . . In the machines we build, the brushes can stand in any position from 0 E.M.F. to full E.M.F. without a particle of sparking upon the commutator, the commutator wearing smooth, and glazing over with any position of brushes.

The machine at the Paris Exposition is a 14in. machine—that is, the exterior dimension of the armature is 14in. The actual exterior dimension of the core when ready for winding is 13½in.

The normal speed of machines of this size is about 1000 revolutions. The E.M.F. of the armature at the brushes, before going through the fields, is about 620 volts, with ten amperes in the fields.

The internal dimension of the core is 10⅛ inches, and the length of the core is 6¼ inches. The insulation in mass of core is 20½ per cent. There are 72 sections in the commutator. There are four layers, with ten convolutions in each layer of wire upon the armature. From these dimensions you can get the actual area of iron.

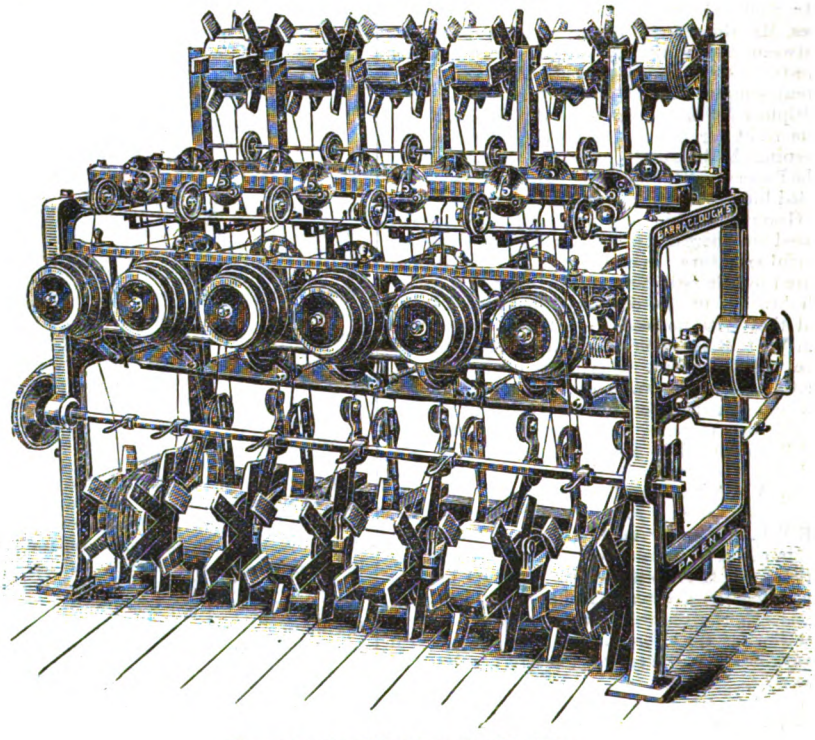
The field is bored perfectly concentric with the armature, and a good liberal clearance is allowed, usually about $\frac{5}{32}$ of an inch exterior to the bands of the armature—perhaps $\frac{1}{32}$ less in the case of small machines.—Yours very truly, ELMER A SPERRY.

Chicago, June 11, 1889.

BARRACLOUGH'S WIRE-COVERING MACHINE.

Among the recent improvements in machinery for insulating and covering electric wires and strands, the machine made by Messrs. Thomas Barraclough and Co., of Globe Works, Manchester, which we illustrate below, shows a considerable advance in the process of covering wires with cotton and other fibrous yarns.

The great desideratum in this branch of manufacture is to obtain a perfectly even covering—the wires must show no inequalities, no thin or thick places ; and in order to effect this the yarns used must be of good quality and even spinning, and the application of the yarns to the wires must be faultless. Considerable difficulty is experienced in arriving at a perfectly even covering, by reason of the breakages of the yarns, the carelessness and want of skill of the operative, and also by defective machinery. The covering heads revolve at a very high speed, the yarns are liable to break, and the bobbins frequently become empty, causing inequalities in the covering, more especially when the attendant fails to observe the breakage or failure of the yarn. The machine has therefore to be frequently stopped, the broken yarn or yarns pieced up, and fresh bobbins inserted in the flyers. During this operation the whole machine is standing still, necessarily involving great loss of production.



Barraclough's Wire-Covering Machine.

The object of this invention is twofold :—1. The construction of wire-covering machines in such a manner that each covering head can be worked and stopped quite independently of the others ; thus, if from any cause one head is stopped, the others are not affected, but continue their work at full speed. 2. The application of an automatic stopping apparatus to each flyer, so that as soon as a thread breaks, or a bobbin becomes empty, the head stops auto-

Digitized by Google

matically and instantaneously, thus preventing imperfect work, and enabling the operative to see at a glance which head needs attention. These machines are usually made with six heads to cover six wires simultaneously, and each head has two flyers with automatic stop motion, arranged to run in opposite directions, so as to apply two coverings to the wire, right and left hand. These heads are quite independent of each other, and can be stopped and started at will.

The following description of one head of the machine will render the mechanism clear to our readers. On the driving shaft, which extends along the machine, a number of discs are keyed, there being one to each head. Adjoining each disc, and to a certain extent covering it, is a grooved pulley. One side of this disc is hollowed, and has a circular leather plate fixed in it, which acts as a frictional surface by which the grooved pulley is driven when pressed up to the disc. Over the pulley an endless band is passed, which drives the two rotating covering flyers in opposite directions. The grooved pulley can be slid upon the shaft by means of a lever, by moving which to the left contact of the frictional surfaces is established, or *vice versâ*. The wire is drawn from the reels—shown in place at the upper part of the machine—and is passed through the hollow spindles of the covering head, after which it follows the course shown until it reaches the draw roller, on which it is taken several turns. The rate of rotation of the draw roller regulates the speed of covering, and the reels upon which the covered wire is wrapped are driven by a band from the shaft on which the draw roller is fixed, so that the speeds of the two are relatively proportionate. The covering material is carried in spools fixed upon pins fastened in the face of the covering flyers. Instead of driving the draw roller shaft by bevel gearing, it is driven by a worm and worm wheel, the former being fixed on the driving shaft. In this way a regular speed of draw-through is obtained, entirely free from the irregularities arising from back lash when ordinary gear wheels are used. This is of the utmost importance to ensure perfectly even covering. The stop motion consists of a small finger attached to the covering flyer in such a way that as the latter is rotated the finger tends to assume a perpendicular position. It carries an eye through which the yarn is passed, the tension upon the latter being sufficient to prevent the finger from taking the position named. As soon as a yarn breaks the finger assumes the perpendicular, and in its rotation strikes one end of a small lever, which is oscillated through an arc of 90deg. The movement communicated to the small lever causes a small mechanism to descend and press a weight, which is suspended by a cord in the slot of a large lever. On the latter is a projection, in front of which the weight is forced, and is thus brought into the path of a cam on the driving shaft. In this way the lever is pressed back, and by means of a connecting rod it raises and releases a small lever, so that it can be drawn over by a spring, and the section is thus stopped in the manner previously described. To re-start the machine it is necessary to piece up the thread and restore the levers to their original position. This is done by a small lifting rod specially provided and arranged to act for both discs.

The machine has met with considerable success, supplying, as it does, a long-felt want; the manufacturer is rendered in a large measure independent of highly skilled labour, whilst the production is relatively much higher than that of other machines, because when one head is stopped the other heads are unaffected thereby. An additional advantage connected with this machine consists in the wide range of thicknesses of wire which can be covered.

ENGINEERS', ELECTRICIANS', BUILDERS', AND IRONMONGERS' EXHIBITION.

Since our previous visit many electrical and engineering exhibits have been added, making the Exhibition complete. Those interested will find a number of excellent displays of electrical and general fittings, instruments, &c., &c.; and of these more particular mention may be made of the stand of Messrs. O. Berend and Co., who have on view some elegant specimens of the metal workers' art, mostly the manufacture of German firms represented here by Messrs. Berend. They also show electrical measuring instruments from the well-known works of Messrs. Hartmann and Braun, of Bockenheim, Frankfort-on-the-Main, and they have a good display of Saxonian bronze ware, for which they are the sole agents in the United Kingdom. At Stand 28, Messrs. Richard Anderson and Co. have on view a good assortment of lightning conductors of all kinds.

The Consolidated Telephone Construction and Maintenance Company (Limited), at Stand 62, show in a small space a large number of telephones, including the Fitzgerald combination telephone, the consolidated telephone, the consolidated magneto-disc telephone, the Austrian consolidated telephone, the Bell and Blake magneto telephone, diving apparatus telephones for submarine communication, and annunciators, call bells, switches, &c., &c., making an imposing exhibit.

Messrs. Richard Johnson, Clapham, and Morris have on view at Stand 74 various specimens of telegraph, telephone, and electric light wires, as well as a number of samples of Johnson's patent rolled wire-lathing, a substitute for wooden laths. It is claimed for the lathing that it will make a building practically fire-proof at a small cost. The makers have several excellent testimonials, one being from a firm in the provinces, who state that a ceiling made of these laths was practically uninjured after being subjected for an hour to intense heat and streams of cold water at a fire which occurred on their premises.

Messrs. Winnall, Callow, and Winnall have since our previous visit completed the installation of the electric light at their Stand 172, and show a number of Newall engines, one of which is driving a 3-unit Phœnix dynamo. The firm claim that the engine has now been perfected, and is especially suitable for electric light purposes. The British Gas Engine Company have at work at Stand 155 a 4 horse-power Atkinson patent Cycle gas engine, driving a 60-volt Statter dynamo direct, supplying a small installation of incandescent and arc lamps; the engine was working very steadily, and Mr. Atkinson informs us that the company are exceedingly busy filling orders. Messrs. Dick, Kerr and Co. have now put down the large Griffin gas engines, which are employed in running a Tyne dynamo (manufactured by Messrs. Ernest Scott and Co.), and a Phœnix dynamo (Messrs. Paterson and Cooper), supplying current to a number of Kent arc lamps.

The Exhibition remains open till to-morrow (Saturday) evening.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 15, 1890.

A Novel Storage Battery.—Messrs. Justus B. Entz and William A. Phillips, of Schenectady, New York, have just been granted a patent for a distinctly novel type of storage battery plate. It consists of a flexible wire, around which is woven a network of finer wire, the metallic oxide being embedded in the meshes of the latter. The plate can be employed either as the negative element of a zinc and carbon primary battery employing a solution of caustic potash, when the hydrogen set free in the cell, tending to coat the plate, will combine with the oxygen in the oxide, depositing pure metallic copper in the meshes of the net-work; or, the same plate may be employed as the negative element of a storage battery, the copper oxide serving as the active material which receives its liberated oxygen during charging. This plate, it is claimed, is uninjured by even the heaviest discharges.

Thomson Electric Welding Process in the Navy.—A very favourable report has been issued by a Board, consisting of Commander George A. Converse, A. S. Greene, Assistant Naval Constructor S. W. Armistead, and Ensign Gilbert Wilkes, U.S.A., appointed by the Secretary of the Navy to investigate and report upon the Thomson welding process. After thoroughly testing and investigating the theories and principles involved, the Board states:—"We are convinced that the Thomson welding process can be found of great utility to the naval service both ashore and afloat, as it can be used for welding breaks in rods without altering them either in length or shape, for welding tubes, angles, and shapes of intricate form, copper, brass, cast-iron and other metals, for heating metals for forging, tempering, and upsetting, and for welding wire cables, and rendering easy many operations in the working of metals which, with a forge and smith, have heretofore been considered impossible." They also remark that as the classes of work at naval stations and on shipboard differ materially, welders designed for use in the two places should be constructed in accordance with the work required of them, those for use on board ship being designed especially to embody lightness, compactness, and general adaptability to the various classes of work which they may be called upon to perform.

The Waite Indicating Dynamometer.—An exceedingly ingenious and novel power meter and indicator has been devised by Mr. Guy Waite to meet the want of an instrument which shall depend upon principles of perfect accuracy, and shall be independent of the elasticity of solids such as springs, the variations

Digitized by Google

of which are a constant source of error; and, further, one which can be readily applied to the machine which it is desired to test, without obstructing any work that it may be at that time performing. This has been accomplished by employing air to receive the power from the shaft, and convey it to the driving pulley of the machine, the power consumed by which is being measured. In the latest type the compression of the air caused by the pull on the belt is in direct communication with a new form of stationary gauge, whose indications may be noted with a great degree of precision. These indications on the gauge are electrically communicated to a recording device, which may be placed at any distance from the machine. The contacts of this apparatus are governed by a rotation of the shaft, by means of which the product of the pull on the belt by the rotation is recorded in an ordinary manner on a system of discs. If it is desired, as in the dynamo, to know how the horse-power varies and what it is at different times under change of load, a continuous diagram of the horse-power transmitted may be taken, showing a record for all times during operation, and also recording the work which is being done. For obtaining a continuous diagram of the horse-power a "speedometer" governed by centrifugal force is made use of.

The Argument on the Right of the City to Transfer the Business of Building the Subways.—This case was argued before Judge Andrews in the Supreme Court on the 5th inst., a large number of legal celebrities and representative electric light men being present. The Manhattan, East River, Northern New York and Mount Morris Electric Light Companies, and George E. Armstrong, taxpayer, moved to have the injunction, granted by Judge Patterson against the Mayor, the Board of Electrical Control and the Consolidated Telegraph and Electrical Subway Company, made permanent, thereby restraining the Mayor and Board of Electrical Control from authorising the transfer by the Consolidated Company of its rights and property to the Standard Company or any other company, and enjoining the Consolidated Company from making such transfer. The vital importance of the issue of the contention to the plaintiffs was dwelt upon by Mr. Nicoll, their eminent counsel, and it was stated that if the proposed arrangements were carried out they would inevitably be driven out of business. The terms of the contract were that the companies should furnish the capital and give suitable bonds. Thirty miles of subways have now been built under this contract. Mr. Nicoll divided the electric light interests of the city into three classes:—The Edison Company, the right to build subways for which is reserved by the Consolidated Company; the Westinghouse interest, which controls the Standard Company, and which includes the Brush Electric Light Company and the United States Illuminating Companies; and the companies other than the Westinghouse, for which companies he appeared. The learned counsel concluded his argument by contending that the Standard Company so far existed only on paper, and contested that the Board of Electrical Control has no power to make another contract, because no breach of contract has been made by the Consolidated Company; and, further, if it has the power to make another contract it cannot authorise the sale or transfer of the subways constructed by the Consolidated Company. Mr. W. N. Cohen, speaking for the Consolidated Company, said that the question of their motives in selling their subways was none of Mr. Nicoll's business. Their money had built them, and they had a right to dispose of them as they saw fit. With reference to the contention of the plaintiffs that their business would be crippled under the new conditions, it was only necessary to remember that the rules controlling those conditions were made by the Board of Electrical Control, and could be changed by the same authority, which would prevent any injustice. It was contended by Mr. Dean that the Board of Electrical Control had power to make new contracts, as the Consolidated Company had been unable to do the required work. Mr. Bourke Cochran, of electrical execution notoriety, stated that the whole proceeding was an attempt of the Manhattan Electric Light Company to extort money from the new Standard Company. This was denied by an affidavit put in on the following day on the sitting of the Court from Mr. Bernheim, of the Manhattan Company. It will be a week or ten days before a decision on the argument can be rendered.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

March 24, 1890.

At the last meeting of the Conseil Municipal it was decided, after some discussion, to extend the concessions for the electric lighting of the Grands Boulevards and of the Rue Royale and Rue Saint Lazare until April, 1891. The lighting has not been of a very satisfactory character, and the extension of the concessions has been granted with a view of enabling the authorities to see the light at work under better conditions before coming to a final decision in the matter. The charges are to be reduced by about 50 per cent., and will be 50 centimes the lamp-hour in the case of the Société Edison, and 45 centimes the lamp-hour in the case of the Société Popp and the Société du Transport de la Force. The number of lamps will be increased from 104 to 131.

The results of the meter competition inaugurated by the municipality of Paris has at last been made public—M. Cauderay 2,000fr., M. Aron 2,000fr., M. Brillié 2,000fr., M. Blondlot 1,000fr., and M. Jacquemier 1,000fr. A new competition, in which any of the above instruments may take part, was officially announced at the same time. [A copy of the rules and regulations in connection with this competition will appear in our next issue.—Ed. *E.*]

The three experts who are to assess the value of the telephone material of the Société Générale des Téléphones are M. Daymard, M. Potier, and M. Paul Josselin, nominated respectively by the Société, the Government, and the Conseil de Préfecture.

The installation at the Asile des Aliénés de Vaucluse has now been in successful operation since November. It comprises nearly 600 lights of 10 and 16 candle-power, and the current is supplied by three compound-wound Desroziers dynamos, giving 740 amperes and 122 volts at 850 revolutions. Owing to the loss in the leads consequent on their great length, the dynamos have been over-compounded, and their terminal E.M.F. varies from 100 to 122 volts, as the current varies from 0 to 130 amperes.

CORRESPONDENCE.

DYNAMO AND MOTOR DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was prevented by illness from attending the discussion on the Papers read by Messrs. Swinburne and Esson at the Institution of Electrical Engineers. I have, however, heard that besides the assertions in these Papers, other assertions were made during the discussion to the effect that the well-known Ayrton and Perry rule concerning motors and dynamos was "nonsense." Even if the persons who use language of this kind gave some reason for their assertion, or showed in any way that they had read our Paper on "Motors" (*The Electrician*, August 11, 1883, *et seq.*); or, at all events, had tried to understand it, I would deprecate the use of such language.

I have been led to read carefully those parts of the Ayrton and Perry Paper on "Motors" which deal with the armature action on the field; and I have been greatly astonished to find that at the date of that Paper, seven years ago, such sound views were held by us. It is a Paper which contains almost everything that has been written since upon the subject, including the Papers of Messrs. Swinburne and Esson. I am not greatly concerned when I find that my views do not meet acceptance from the members of our profession, and, as a rule, I care very much less about what I have done than about what I hope to do. But I had forgotten the "Motor" Paper, and have been compelled to study it, and I cannot restrain my admiration, which is that of a nearly unbiassed critic.

Since the publication of Dr. Hopkinson's theory of the magnetic circuit of a dynamo it is obvious that the statement

$$F : A :: \frac{WC}{1+SC} : \frac{W'C'}{1+S'C'}$$

is antiquated. It is much better to take, as we do in page 35, F and A as the ampere-turns on the field-magnet and armature respectively. In either case, page 35 is right so long as saturation is not approached. When saturation is approached, instead of taking the above antiquated expressions, we have now simply to say that

$$F \cos\phi \mp A \sin 2\phi$$

Digitized by Google

represents the total ampere turns producing the actual field to which the E.M.F. is proportional. It will be observed that every curious result obtained by Mr. Esson and other experimenters which have appeared to be so complicated and difficult to understand, are at once obvious from the expressions we have given.

I presume that it is now too late to get any of our assertive critics to really read the Paper on "Motors." They simply say that there is no difference between a dynamo and a motor. Is it too much to ask them to study the following statement? It puts the whole disputed position in a nutshell.

Imagine a machine in which the armature current increases the field. Obviously the coil which is just about to be short-circuited has an E.M.F. acting in it which is in the same direction as when this coil was acting most usefully—that is, if the machine is a motor this E.M.F. is *opposing* the current. But this is the very kind of E.M.F. which is required when a coil is being short-circuited if sparking is to be destroyed. Now imagine the same machine to be a dynamo, and speak again of a coil which is just about to be short-circuited; the E.M.F. in this coil is in the direction of the current, and this is the very kind of E.M.F. which will cause destructive sparking. Thus, then, even if we assume no time-lag of magnetism—which I firmly believe in—we have the essential difference between a dynamo and motor on which Prof. Ayrton and I have always insisted, and on which our theory depends.

After writing the above I received, as an invalid, the kind visit of Prof. Fitzgerald. He put the matter in another and more general way. "From the doctrine of reversibility, a good dynamo is a good motor, but this is on the assumption that the action is reversible. Now, sparking is a non-reversible action, and on this account alone there must be a difference between a dynamo and a motor."—Yours etc. JOHN PERRY.

10, Penywern Road, S.W., March 24, 1890.

MAPPING THE WASTE FIELD OF DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my very hurried remarks on the last evening of the discussion of Messrs. Swinburne and Esson's Papers, I had no time to properly explain the diagrams which I then exhibited, and of which I have sent you photographs. I should, therefore, be glad if you would give me space to make one or two observations about them. The lines were produced by a series of impressions from a soft iron needle faced with india-rubber. The needle was, in the more satisfactory diagram, about half an inch long, three sixteenths wide, and about one-sixteenth thick. It was pivoted freely on a pin. The ends were pointed, and thus the impressions could be fitted heel to toe to form a continuous line. The line terminated when the field became so weak that the direction of the needle became uncertain.

The first object I had in making the experiment, which I was enabled to carry out by the courtesy of Messrs. Goolden and Co., and with the assistance of Mr. Vignoles, was to ascertain how far the assumptions made by Prof. Forbes in the three lemmas given by him in 1886 were consistent with what actually happens in practice. A secondary and interesting object was to produce evidence of the distortion due to cross magnetisation, described by Mr. Swinburne.

The machine with which the first three experiments were made was a Goolden-Trotter 2½ unit. A piece of cardboard was cut to fit the profile of the machine, and the field was excited with the normal shunt current of four amperes. The impressions of the rubber-faced iron needle were made starting at uniform distances of one inch apart on the upper pole-piece. Those that reached the lower pole-piece meet it at smaller intervals. This appears at first sight as though the magnetic potential was greater here, because one is accustomed to the apparent crowding together of the lines in a diagram produced by iron filings, but the density of the lines in these diagrams has not necessarily any connection with the magnetic potential. The crowding together of the lines is, I believe, due to the fact that the machine was placed on an iron bedplate, and this caused a distortion of the lines which did not primarily crowd them together, but produced a greater curvature in the lower half of each curve, and from the fact that each impression followed heel to toe they tended to crowd together on account of this increased curvature. The point is worth considering, and could be cleared up by further experiments.

The second and third experiments, in which the armature was held fast, for convenience, show the distortion very clearly. The fourth was to show the leakage in an extreme and complicated case, in which the great effect of the shaft, which runs in babbitted bearings, is very marked.

I hope at another time to supplement a complete map of the stray lines in two or more principal planes by lines of equal strength of field, by a snap coil and ballistic galvanometer. From the two series of curves thus found one should be able to find a certain line of force, which may be taken as the mean line, whose length is a measure of the fall of magnetic potential from one plane to the other, and should be comparable with this quantity, as calculated by Prof. Forbes' method.

I was induced to make these experiments, which I first carried out in 1884 or 1885, partly by noticing the imaginary and, I believe, somewhat incorrect lines of force drawn in Mr. Swinburne's diagrams. I have not mapped out the lines between the magnets and the shaft of an ordinary Gramme type dynamo, but from what I have seen of the behaviour of a needle there, they would be well worth examining.—Yours, &c., ALEXANDER P. TROTTER.

THE PFANNKUCHE ALTERNATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of February 21, 1890, I find a Note under the heading "An American Re-invention" (on page 387). If, according to said Note, the *Electrotechnishe Zeitschrift* has published a description of the "Pfannkuche Alternator," and used cuts belonging to the "Mordey Alternator," that does not, in my opinion, justify you in applying to my alternator the opprobrious appellation of "Re-invention." In the *Electrotechnische Anzeiger*, of Berlin, I some time ago stated my claims of priority, which can and will be duly enforced, as a patent has been granted to me in England; and I can prove that priority, if rushing into print and publication do not constitute priority of invention before the law. If Mr. Mordey is sure of his prior claims, let him come into our Patent Courts here, and we will soon see what his claims are worth. Your paper has the reputation for independence and fair-dealing, and I appeal to your sense of fairness to see that my interests and reputation are not damaged by uncontradicted statements from wrongly informed parties. Thanking you beforehand for publishing this notice at your earliest convenience,—I am, Yours, &c.,

GUSTAVE PFANNKUCHE.

Cleveland, Ohio, March 7, 1890.

FIXING MAGNETIC CURVES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The process described on page 488 of *The Electrician* of March 21, 1890, for fixing iron filing curves, quoted from *La Lumière Electrique* as the invention of M. Korobow, is by no means novel. It has been regularly used in the physical laboratory here for many years.—Yours, &c.,

W. W. HALDANE GEE.

The Owens College, Manchester, March 21, 1890.

LEGAL INTELLIGENCE.

Garman v. Brighton and Hove Electric Light Company.

This was an action heard yesterday (Thursday) in the Sheriffs' Court, Holborn, in which Emma Garman, of Brighton, sued the defendant Company to recover £1,000 as damages for the loss of her husband, who was killed by a shock from one of their wires. Mr. C. Chapman and Mr. Higgins were counsel appearing on behalf of the plaintiff; and Mr. Pike and Mr. Ruegg represented the defendants.

In opening the case, the learned counsel said that one of the Company's electric light wires was hung over the premises of Messrs. Abby and Hallett, brewers. The plaintiff's husband, T. H. Garman, was employed there as an engineer and night watchman. On the night of July 14, 1889, his duty required him to attend to a vat on the top of the building. A wire, it was admitted on the part of the defendant Company, was negligently hung in

Digitized by Google

a drooping condition, and the deceased accidentally touched it, and was killed on the spot. He (the learned counsel) asked the jury to award the widow and children fair and reasonable compensation.

Dr. LOWE deposed that he conducted the post-mortem examination on the deceased's body. He was astonished at the healthy condition of the man, who had evidently been struck by a wire containing over 2,000 volts of electricity. This was the immediate cause of death.

This evidence was objected to by Mr. Pike, although the defendant Company admitted that the wire was fully charged.

An actuary proved that calculating a man's life from insurance grounds, at the age of 32, and a weekly wage of 22s., the amount would be £1,090. 12s.

The Jury, after a short consultation, returned a verdict for the plaintiff, and awarded £800 as compensation: £200 for the widow, and £100 for each of the children.

Judgment was accordingly entered with costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

SPANISH TELEPHONES.—We notice in a French paper that tenders are invited for the installation and working of telephone exchanges at Burgos and Gerona. Particulars are not given as to whom the tenders are to be sent, but we presume to the leading public functionaries of these towns. Tenders have to be in, for Burgos by April 10, and for Gerona by April 11.

ELECTRIC TESTING STATIONS.—At the meeting of the London County Council on Tuesday, the tender of Messrs. Latimer Clark, Muirhead, and Co. was accepted for the supply of a gas-engine and dynamo for £453 10s., for the electric testing stations to be established in Cranbourne-street.

PLANT FOR SALE.—The Liverpool Electric Supply Company have completed their new central stations, and have a large surplus plant for disposal, consisting of Crompton, Siemens, and Brush dynamos, engines and boilers by Messrs. Marshall and Co., a Crossley gas engine, belting, cables, arc lamps, &c. Further particulars and prices can be obtained at the offices of the Company, 15, Highfield-street, Liverpool.

MESSRS. POOLE AND WHITE (LIMITED).—This firm, who recently commenced business at 58 and 59, Bread-street, London, E C., are now fairly settled in their commodious premises, where they have on show a choice selection of electric light fittings, globes and shades, switches, ceiling roses, &c., &c., many of which are of excellent design. The firm have on hand a number of choice original designs, which they will shortly include in their list. When the few remaining alterations are completed, Messrs. Poole and White will have one of the largest show-rooms in London, in the heart of the City. We understand that the firm are very busy, which indeed seems to be the case throughout the trade.

THE "AUDIO" TELEPHONE MOUTHPIECE.—This mouthpiece, known as the "Cotterell Whisperer," is now being generally introduced. It is specially designed for transmitters of the "Blake" type, but it is equally suitable for use on instruments of the "Gower-Bell" form. The "Audio" is easily fixed to the telephone by means of brass clips; when thus fixed conversation may be carried on in so low a tone that anyone in the same room as the person speaking is unable to hear the speaker's voice, while at the same time the conversation is carried over the circuit with perfect distinctness. The "Audio" is supplied by the Audio Telephone Mouthpiece Company, 15, Ann-street, City, Glasgow.

MESSRS. STANLEY, MORRISON AND CO.—We have received from this firm a circular giving prices and particulars of their various makes of india-rubber goods; and also of Morrison's special asbestos metallic rolled packing, &c.

SOUTH OF ENGLAND TELEPHONE COMPANY (LIMITED).—This Company are issuing a neat pocket guide to the public call offices in Lynn and Peterborough, also giving instructions how to use the telephone. Accompanying this is a list of the present subscribers to the King's Lynn Exchange, which shows very clearly the extension of the telephone in that part of the country.

THE PHONOGRAPH.—We are authorised to state that the reports which have been current in regard to the simplification of Edison's Phonograph by a person named Fossati are without foundation. They arose from the fact that a German gentleman visited Milan with one of Mr. Edison's latest machines—a much later pattern than has been generally introduced to the English public—and Mr. Fossati was merely indirectly interested in the exhibition of it. The galvano-plastic reproduction of cylinders mentioned in connection with Fossati has received the attention of Mr. Edison during many years, and in 1878-9 he invented a method of duplication of phonograph records by it.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

February 17, 1890.

2,527. O. CORNWELL. Brighton. Improved method for the regulation of the carbons in electric arc lamps by the expansion and contraction of metallic wires.

February 18, 1890.

COMPANIES' MEETINGS.

The Direct Spanish Telegraph Company (Limited).

The thirty-third ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on the 24th inst., under the presidency of Sir James Anderson.

The MANAGER (Mr. Charles Gerhardi) read the notice calling the meeting and the minutes of the last meeting, which were confirmed by the present meeting, and signed as correct.

The report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, you will see by the report that we have earned £1,592 in excess of the amount realised in the corresponding period of last year. To earn this we have carried 17,260 more telegrams, or 155,192 more words, and I am pleased to observe that for this half-year under review there has not been any further decrease in the length of the messages; the average length is 10·48 words, and this condition has now continued for twelve months. There has been, ever since code-language and the word-tariff pure and simple (that is, a single word, which we can

Digitized by Google

only charge for) were introduced by the companies, a steady persistency on the part of the users of the cables to reduce the number of words in their telegrams, until at last we have reached the point at which 35 per cent. are below five words; and the average is, as I have already said, 10·48 words. The companies do not complain at the reasonable endeavour on the part of the telegraphing community to reduce their expenses for telegrams; but we own freely that the compilers of codes have so brooded over the subject, and worked out all the combinations and possibilities of code-language, that the result has greatly exceeded the economic possibilities that we considered possible when we agitated at the different Conferences for the adoption of code-language and the word-rate pure and simple. Were the reduction in the length of telegrams to stop where it now is, we might take comfort from the fact that merchants can now use the telegraph for small transactions—for business that may come to nothing, and for inquiries that lead to no profitable result. We might expect that telegraphy would continue to grow. The growth of telegraphy is no doubt due to such causes amongst many others. It is now cheap enough to admit of the smallest transactions being carried out by telegraph. The result of that is that we find in practice that when merchants abroad, brokers, and others, see a ship coming in or hear of business, they send a word off—a small telegram—to their correspondents, asking to be permitted to do some transaction. This is a phase of business which could not be done if the tariff were high. Therefore, we do not look with horror on cheap telegraphy, especially where there is a large community likely to use it. That is one of the advantages we have in dealing with a Continental State like Spain, which seems to be growing in commercial transactions, and more alive to commerce than it used to be. We therefore need not despair as to the traffic continuing to grow. Unfortunately, whenever there is a reduction of tariff there is a loss to begin with, in some important instances a prolonged loss, which is disappointing, and very different from the result we were encouraged to expect by the reduction of tariff. In the case of this Company, we are now working at a tariff so low that we have a right to expect that we had established a minimum charge; but we are not so sure of this as we would like to be, as we know that at the coming Telegraph Conference to be held in May of this year there are some new terrors proposed, and some administrations look with an unfriendly eye upon our poor 4½d. per word. Happily there are other telegraph administrations which consider this game of reduction has gone too far, as the great majority of the European States are losing money on their telegraph service, and they do not like it. I am not telling you all this without some point. I am supposing that some of you have examined the balance-sheet and have noticed that we are carrying forward a sum unusually large for this Company; and that to earn this £1,592, and transmit 155,192 more words, our expenses have increased by £690, not all due to salaries, but some of it to the increased rent and taxes for larger premises, more stationery, more printing, more new instruments and improvements at our stations; also there is the rent for the unexpired lease of the old office in Leadenhall-street, which will not recur; but after all that is said, we are paying you 6 per cent. and carrying forward a fair sum of £846. 18s. 2d.; and your Directors desire to cling to this sum not only because the action of the Conference may still further affect our revenue, but also for another reason. Should our prosperity continue, we shall act prudently if we look forward to a greater or lesser amount of special reserve for the reduction of our Debenture debt. This we consider due to our Preference shareholders. You know we have £62,000 of Debentures at 6 per cent.; and some plan ought to be adopted, when they are due in 1894, to deal with them, either by a special reserve, or by calling up the £1 per share still uncalled, or by an increase of ordinary capital, which may be issued at a premium if we continue fortunate, or the Debentures may be renewed at a lower rate of interest if our reserve is as good as we hope it will be when the time comes. These are points before your Board affecting the policy they may desire to adopt as time goes on. I hope, then, you will consider that so long as we pay a 6 per cent. dividend we are only acting prudently in laying by as much more money as we earn above that 6 per cent. I sincerely hope we may continue to receive that 6 per cent.; but I by no means pledge myself to any opinion. We may have another interruption of our cable. We do not know what proposals may be made by the Telegraph Conference (some of them may hurt us or may not), and we feel that 6 per cent. is as much as we ought to divide for the present. I am happy to be able to state that France has given us the use of a direct special wire between the Paris Bourse and our Marseilles office, so that the transmission of our telegrams to and from Barcelona is much accelerated, and our traffic in consequence has increased. Spain has also given us a good wire from Bilbao to Madrid, and our traffic is at present increasing, and our new office in Gracechurch-street is realising our anticipations. I have before me all the items upon which there has been any increase of expenditure, should any honourable proprietor care to ask for further information. Unless you ask me questions I think I have said all that can be usefully said. I move—

"*That the report and accounts now presented be and they are hereby received and adopted.*"

Mr. E. ETLINGER seconded the motion.

The CHAIRMAN invited discussion, but no shareholder rising to address the meeting, he put the resolution, which was carried unanimously. He then proposed:—

"*That the dividend at the rate of 10 per cent. per annum, less income-tax, on the Preference shares, and a dividend at the rate of 6 per cent. per annum on the Ordinary shares, free of income-tax, both for the half-year ended December 31, 1889, be and are hereby declared.*"

Mr. ETLINGER seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. J. DENISON PENDER, Mr. E. Etlinger was re-elected a Director; as was also Mr. J. Denison Pender, on the motion of the CHAIRMAN, seconded by Mr. ETLINGER.

Mr. WALTER BARNETT then proposed the re-election as auditor of Mr. Herbert R. Duke, with a remuneration of twenty guineas. That was an increase of Mr. Duke's remuneration; and he thought it was justified, having regard to the fact of the increased prosperity of the Company, and consequently, as he would suppose, of his augmented work.

Mr. DYETT seconded the motion, which was carried unanimously.

Mr. DUKE acknowledged his re-election, and said that when he first became auditor, on the death of the late auditor eight or ten years ago, the accounts were not so voluminous as they were at present. He was very much obliged to the shareholders for the increase in his remuneration. The work of auditing the accounts took himself and a clerk the best part of a week twice a year. He congratulated them on the satisfactory report which had been presented that day.

Mr. LOWE then proposed the following resolution:—

"*That in the opinion of this meeting the Directors' remuneration should be now increased beyond the sum of £400 per annum, and that in view of their declared intention not to avail themselves of their rights under the 71st of the Company's Articles of Association as it now stands, the Directors be and are hereby requested to give notice of a special resolution being brought forward at the next half-yearly meeting for altering Article 71 so as to increase their remuneration to £600 or otherwise, as may from time to time be voted in general meeting.*"

Mr. BARNETT seconded the resolution.

The SOLICITOR (Mr. Blunt): The Articles of Association prescribed that the Directors should receive £400 a year, with an additional sum of £100 for each 1 per cent. dividend paid to the shareholders above 6 per cent. It is understood, apparently, by the terms of the resolution, that the Directors do not desire to avail themselves of that power. I believe that they have been influenced by the fact that the shares are not of the same magnitude as they were when that Article was written, and 6 per cent. is paid on a lower capital than when the Article was introduced. I understand that in consequence of that this resolution is proposed as, in point of fact, an alteration of this Article; and, as most gentlemen present are aware, an Article cannot be altered without a special resolution; that requires special notice, and I understand that this resolution is a request to the Board to bring forward a resolution at the next half-yearly meeting dealing with this matter.

Mr. COCHRAN inquired whether the altered circumstances of the Company made any alteration in the Articles of Association necessary.

The SOLICITOR replied that as a matter of law he would say that the Articles still held good, and therefore the Directors would be entitled, on paying an increased dividend of 1 per cent., even on the reduced capital, to the extra remuneration mentioned in the Article; but their feeling was that they would rather leave the fixing of the remuneration above £400 to the meetings from time to time.

The CHAIRMAN having read the resolution again,

A SHAREHOLDER asked, "What does 'otherwise' mean?"

The SOLICITOR: It leaves power to the general meetings to alter the remuneration from time to time.

The CHAIRMAN: Even to reduce it?

The SOLICITOR: Even to reduce it.

Mr. DYETT inquired whether what was proposed would be an increase or a decrease on what the Directors were entitled to.

The CHAIRMAN: An increase. We should have been entitled to that last year according to our lawyer's opinion, but we want to see what will happen. We are not very eager about it. By next October we shall know something more than we do now. He then put the resolution, which was carried unanimously.

Mr. JOHN NEWTON proposed a vote of thanks to the Chairman and Directors for the satisfactory position to which they had brought the Company. He was very pleased to hear that the next Telegraph Conference was going to be held so soon, for he was one that liked to be out of his misery at once. The telegraph shareholders looked forward to this Conference with something like fear, and he was glad to hear that at the next Conference there would be representatives who thoroughly understood the position of telegraph companies, not only here but on the Continent. He would not, however, like the representatives at the Conference, to express the opinion which the Chairman had expressed, that coding had reached its perfection, because he did not think that the users of the telegraph had reached the full power of taking advantage of telegraphic communication. Telegraphing was now done so cheaply, and the more cheaply it could be done the more business they would have. It was to his mind impossible to say that it would not be within the reach of merchants to telegraph cheaper than they did now, by means of codification. He had had a great deal of experience in seeing the development of the coding system. He remembered the very early days, when it was scarcely possible to express fully what was required in twenty words, but at the present time they could express in three or four words as much as a few years ago they could convey in twenty words.

Mr. DYETT seconded the motion, which was carried unanimously.

The CHAIRMAN: I may say a few words more about the coding question. I may tell you that we have now got to this point, that we make about a halfpenny a word net from a telegram. If you come to reduce that you will see that it is a new terror to us. All the Continental States who have low tariffs are losing money. Fourteen of them are losing money, and only six are making a fraction above their expenses. It is all very well when you can tax people to cover a deficit, or when you can make it appear, by fusing the Telegraph and Postal services together, that you are making a general profit. We, however, in these companies cannot tax anyone. We are working very low. The average number of plain words conveyed by each code word is 8 or 10, so that the tariff is really for 8 or 10 words that merchants are charged. We do not complain, however, because we introduced this system; but you may go too

Digitized by Google

far. As it is, at the forthcoming Conference one State proposes a minimum of five words, and another proposes ten words; so you see they are feeling it. Another State proposes that a double charge should be made for coding messages. We are not in favour of the latter. We have met frequently, and have thrashed out everything that has been proposed by the different States. We shall go to the Conference primed with knowledge, but what will happen at it we cannot say, as side issues arise. We never know what may happen, therefore I am always glad when these Conferences are over, and we have again five years' peace. I hope when we meet next October I may be able to speak cheerfully about the Conference.

The proceedings then terminated.

The Telephone Company of Egypt (Limited).

The seventh ordinary annual general meeting of the shareholders in this Company was held on Tuesday at the offices, 14, Austinfriars, London, E.C., under the presidency of General Alexander Fraser, C.B., R.E.

The SECRETARY (Mr. A. B. Chalmers) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, I do not think I have much to add to what is stated in the report of the Directors. As you are aware, we are now established in five places in Egypt, viz., in Alexandria, Cairo, Mansourah, Zagazig, and Port Said; and we hope soon to be able to increase the number of installations. We are now in negotiation with the Government to endeavour to establish one at Assiout. I am happy to say with reference to our Port Said installation that it has been very energetically established by our manager. We have been able, by the help of our colleague, Mr. Grewing, to see Sir Rivers Wilson, and to secure his co-operation in obtaining from the Suez Canal Company permission to place a cable across the Canal to give telephonic communication with the other side of the waterway. The Company has also given us a subscription, and this will not only enable us to increase our subscribers at Port Said, but possibly at other places on the Canal up to Suez. Since we last had the pleasure of meeting you we have lost one member of our Consultative Committee in Egypt in the person of Mr. Chapman, who was agent of the Peninsular and Oriental Company, and who resigned on his return to this country. In our report we have said that we do not expect a great development of business at Cairo and Alexandria for the present; but I think myself that when the prosperity of Egypt increases, our business in telephones will also increase. With reference to the resignation of Mr. Chapman from the Consultative Committee, we have thought it well to appoint a gentleman as a member of the Committee who has been very useful to us, Mr. A. J. Manuk, and since his appointment he has been very useful to us in our relations with the Government and their functionaries. I do not think there is anything more for me to say in the matter. I should like to remark that our business in Egypt has been very ably carried on by our manager, Mr. Evans, who has proved himself, I think, to be thoroughly up to the work, and conducts the business which his late father carried on with all the energy and ability of a young man. We have at Cairo also in the person of Mr. Begni an able and satisfactory manager. I think the shareholders are quite justified in giving their thanks to these gentlemen and the staff in general in Egypt. The work has been carried on in London, too, by Mr. Chalmers and staff in a very satisfactory manner. Unless you have any questions to ask I beg to move:—

"*That the report of the Directors and statement of accounts be and they are hereby received and adopted, and that a dividend be paid of 6 per cent. on the Preference shares, free of income-tax.*"

Mr. HENRY GREWING seconded the motion, which was agreed to.

On the motion of the CHAIRMAN, seconded by Mr. GREWING, the retiring Director, Mr. Thos. Lloyd, was re-elected to his seat at the Board.

The Auditors, Messrs. Price, Waterhouse and Company, having been also re-appointed,

A vote of thanks to the Chairman and Directors was passed, and the proceedings terminated.

Newcastle and District Electric Lighting Company (Limited).

The second annual meeting of this Company was held on the 19th inst., at the Crown Hotel, Clayton-street, Newcastle.

Mr. J. D. Milburn presided; and there were also present, Sir Benjamin Browne, the Hon. C. A. Parsons, Mr. H. C. Harvey, Mr. J. B. Simpson, Mr. F. J. Snowball, and Mr. J. Patterson (secretary).

The following report of the Directors was taken as read:—The Directors have to report that the Company's central electricity supply station is now in full working order, and that up to the present arc and incandescent lamps equivalent to 2,100 ten candle-power lights have been connected to the mains of the Company, and the work is proceeding for switching on further lamps, equivalent to 3,500 ten candle-power lights. The Directors anticipate that in a very short time the Company will have sufficient business to take up all the electric current which the present plant is capable of supplying. The delay in receiving the Board of Trade licence for the Company to proceed has been got over by the Directors being able to come to a private arrangement. It is as yet too early to give an accurate forecast of the financial prospects of the Company, but the Directors have no reason to alter the favourable opinion as to the future of the Company that they have always held.

The CHAIRMAN, in moving the adoption of the above report, referred to the difficulty which arose in consequence of a technical error in the draft Board of Trade licence at the moment that the licence should have been handed to the Company. He said that after waiting several weeks the Directors resolved to appeal to the Mayor and Corporation for leave to lay down their mains pending the receipt of the licence from the Board of Trade. The Corporation considerately granted the Company's request under certain conditions, and every effort was put forth by all connected with the working of the Company to make up for lost time. In order to minimise the inconvenience to the public through the lifting of the flags and crossings, an arrangement had been made between that Company and the Newcastle Electric Supply Company for the division of the town into two areas, with the exception of the Quayside, which was to be open to both companies. As regarded prospects, business was flowing in steadily. The total number of 10 candle-power lamps which could be efficiently connected to the Company's stations, as at present completed, would be about 9,000, and of these probably not more than 6,000 or 7,000 would be simultaneously in use, thus leaving one generating machine and boiler always in reserve. Up to the present the Company had connected with their mains 41 installations, representing from 3,000 to 4,000 10 candle-power lamps, and orders for current have been given for about 1,500 or 2,500 more, and many others were in prospect. It would appear, therefore, that the Company would shortly have more business than it could manage without increasing its generating power, and very shortly it might be necessary to expend more capital to make such increase. Owing to the special system of the plant and machinery, that could be done gradually. When selecting the generating station the Company took care to secure a building of such capacity as would allow the increase of plant to any degree likely to be demanded by future requirements. The present building at Forth Banks would permit of the generating plant being doubled, and the Company had the option of acquiring the building adjacent thereto. Including this second building, the Company would have space for generating-plant equal to eight or ten times its present productive power, which would represent something like the simultaneous running of 50,000 or 70,000 lamps installed. Their Managing Director, the Hon. C. A. Parsons, had recently been experimenting with arc-lighting in conjunction

with the alternating-current system, which was the system adopted by the Company. Large arc-lights at the Tyne Theatre, the Company's offices, and the generating station had been very successful, and the Directors believed they would be enabled to undertake at an early date a portion of the lighting of the city streets where brilliant illumination was desired. Presently they might look forward to getting some use for their current during the daytime. In America electricity was becoming quite the fashion for motors of every description, lifts in hotels, overhead railways, printing presses, &c., and that Company meant to encourage its application to some of those uses to the utmost extent. But it was to the tramways that they must turn their anxious attention. He believed that the Directors of the Tramway Company would not remain long in the background so soon as a reliable and profitable scheme for electric traction could be indicated to them. Last year, in announcing the policy intended to be pursued by the Directors of that Company, he said that there was no intention to enter into any insane competition or death-grapple with gas. It would be some time yet before electricity would vie in cheapness with gas. With arc-lighting it was different. There was no doubt that the electric light would cause an increased use of gas in the city, for the brilliancy of the illumination secured by those who used it would cause the users of gas to use much more of that illuminant. He believed that shortly the fire insurance offices would look upon houses lighted by electricity as the safest of their risks. In conclusion, the Chairman stated that the light had given entire satisfaction, and the Company had not had a single complaint.

Sir BENJAMIN BROWNE seconded the motion. He thought the electric light was very popular.

The report was adopted.

Sir B. C. Browne and Mr. A. F. Wade, retiring Directors, were re-elected; and Messrs. Strachan, Hill, and Co. were re-elected auditors.

The meeting then terminated.

NEW COMPANIES REGISTERED.

DURAND ELECTRIC, PETROLEUM AND GAS ENGINE, AND MANUFACTURING COMPANY.—Objects: To take over and carry on as a going concern the business of Eugene Durand, at 163, Avenue Victor Hugo, at Paris, and elsewhere, and acquire and work patents and inventions, belonging to and connected with or for the purposes of the said business, the exact nature of which is not specified in the Memorandum of Association. Capital £100,000, in £10 shares. Registered March 15th, without Articles of Association, by Henry Martin Green, solicitor, Havant, Hants.

ELECTRIC METER COMPANY.—Objects: To carry on the trades or businesses of electricians, mechanical engineers, and manufacturers, and to purchase and carry into effect certain letters patent relating to electric meters and other rights and things, entering therefor into an agreement with the Corporate Trust, Limited, (incorporated August 30, 1889, with a capital of £50,000 in £10 shares), the particulars of which are not specified in the Articles of Association. Capital, £50,000, in £10 shares. Borrowing powers unrestricted. Registered, March 22nd, by Walter Webb and Co., solicitors, 23, Queen Victoria-street.

CITY NOTES, &c.

AMERICAN BELL TELEPHONE COMPANY.—The statement of this Company for the past year shows a net increase of $247,683, and a surplus after payment of dividend and all charges of $122,975, the total surplus being $2,151,011.

ANGLO-PORTUGUESE TELEPHONE COMPANY.—An interim dividend at the rate of 4 per cent. per annum (less income tax) has been declared upon the share capital of this Company.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended March 21st amounted to £5,176.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment on April 15th next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the Preference shares of the Company, for the quarter ended March 31st current, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended December 31, 1889. The register of transfers will be closed from April 8th to 15th next, both days inclusive.

EASTERN EXTENSION TELEGRAPH COMPANY.—The accounts of this Company to December 31st show, subject to audit, a balance of profit of £139,744, after payment of three interim dividends. The Directors now propose to distribute on the 23rd prox. a dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1889. It is proposed to pay a bonus of 4s. per share, equalling 2 per cent., making a total distribution of 7 per cent. for the past year. The balance of £58,494 has been carried to the reserve fund, which now stands at £710,113. The register will be closed from the 16th to the 23rd prox. inclusive.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—This Company was put upon the market last week, subscriptions being invited for 100,000 Ordinary shares of £2 each at a premium of £1 per share. The total capital of the Company is £300,020, divided into 150,000 Ordinary shares of £1 each and ten Founders' shares of £2 each. Half of the premium on the shares now issued is to be carried to a reserve fund, and the remainder is to be paid to Elmore's Patent Copper Depositing Company (Limited). The Board includes five Directors of this last-named Company, who will join after allotment, one of the other Directors being Mr. William Elmore. The Company expect to receive large orders for wire for electrical purposes in connection with telegraphic and cable services and central lighting stations, and claim for its process many advantages over existing processes. The purchase-money to be paid by the new Company to Elmore's Patent Copper Depositing Company (Limited) is £75,000, half the amount of the premiums (as stated above), and the allotment of the ten Founders' shares of £2 each, which are to receive no dividend until 20 per cent. has been paid upon the Ordinary shares in any year, after which the surplus profits will be divided, as to one moiety, between the holders of the Ordinary shares, and, as to the other moiety, between the holders of the Founders' shares. The list opens this day (Friday) and closes on or before to-morrow (Saturday). Objects: To carry on the business of metallurgists and makers of and dealers in metals, and metallic alloys, and particularly to acquire from Elmore's Patent Copper Depositing Company (Limited), under an agreement, patent rights and privileges, and to carry the same into effect. Letters of allotment and regret were posted this week.

GLOBE TELEGRAPH AND TRUST COMPANY.—The Board of this Company notify an interim dividend of 2s. per share, payable on the 18th proximo.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED).—This Company notify that share certificates are now ready, and can be exchanged for the banker's receipts for amounts paid on application, allotment, and first call.

SCHOOLING AND CO. (LIMITED).—The Directors of this Company have declared a dividend of 5 per cent. for the last six months, making, with the interim distribution, 10 per cent. for the past year.

STOCK EXCHANGE.—The Committee have appointed Wednesday, April 9th, as special settling day for the following securities, which are also ordered to be quoted in the official list:—Crompton and Co. (Limited), Preference Shares Nos. 1 to 20,000; United River Plate Telephone Company (Limited), £146,128 Five per Cent. Debenture Stock (part of £200,000 authorised); Westminster Electric Supply Corporation (Limited), Ordinary Shares Nos. 101 to 42,953.

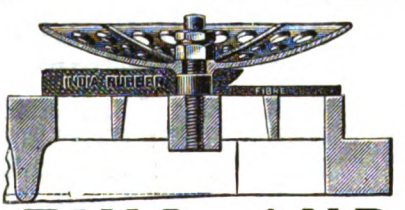
VICTORIAN SCHANSCHIEFF ELECTRIC LIGHT AND POWER COMPANY.—The *Melbourne Argus* reports that this Company has gone into liquidation.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.—The traffic receipts of this Company for the week ended March 21st, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,991.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—Lord Suffield (the Chairman) presided on Wednesday at a confirmatory meeting of the shareholders, held at the offices, 4, Victoria-mansions, S.W., which was called for the purpose of approving of certain resolutions proposed at a previous meeting, altering one or two of the Article of Association. The Chairman having formally submitted the resolutions, they were unanimously adopted.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 620.—Vol. XXIV. FRIDAY, APRIL 4, 1890. Price Fourpence.

NOTES.

The interesting Paper read last week at the Institution of Electrical Engineers by Dr. Harries and Mr. Newman Lawrence evoked considerable comment, and will probably give rise to still more. The results brought forward by the authors of the Paper are, it is true, by no means new. It has long been known that the resistance of the human body to alternating currents is considerably lower than its resistance to continuous currents. It has also been the painful personal experience of most electricians that the "shocking" properties of an alternating current are decidedly superior to those of a continuous current; although in this respect the palm is awarded by many to the current from a Brush arc-light machine. The interest of the Paper lies, however, in the fact that it is a plain statement of the results of a painstaking and impartial investigation of a subject in which accuracy and impartiality have hitherto been conspicuously lacking. Considering, however, the wide difference between the conditions which obtained even in the experiments in Table E, and those which are likely to obtain in the case of accidental contact with electric light wires, the deduction of such a formidable looking "danger ratio" was, we think, hardly warranted. As we remarked in connection with the nauseating experiments of Mr. Harold P. Brown and others, the question at issue, so far as electrical engineers and the public are concerned, is a very straightforward one. It is simply whether the dangers of high-tension alternating currents so far outweigh their advantages that they ought to be absolutely prohibited. With ordinary care and good workmanship the "danger ratio" may be made to very closely approximate unity.

The statements made by Mr. J. S. Forbes at the meeting of the shareholders of the London Electric Supply Corporation on Monday last, together with Mr. Ferranti's report, render the present position of affairs at Deptford tolerably clear. Two 30,000-light dynamos working at one-quarter their proper voltage are, it must be confessed, a most discouraging result after two years' hard work and an expenditure on plant and machinery alone of over £68,000. But the building of a colossal generating station at a great distance from the centre of supply, the employment of abnormally high pressures and of abnormally big dynamos, all tend to make the Deptford scheme, although grandiose in conception, an enterprise, to quote the Chairman's words, "involving a great many speculative quantities and something also risky." That the many difficulties which are now being encountered by Mr. Ferranti may be triumphantly overcome is, we are sure, the wish of electrical engineers all over the world. Meanwhile there is nothing for it but to exercise that patience so frequently recommended by the Chairman in the course of his long and somewhat disconsolate speech, and to trust the confident tone still assumed by Mr. Ferranti will be more justified by the successes of the future than it is by the events of the past.

Some interesting facts with regard to the magnitude of the Corporation's operations may be gathered from the accounts, which, as last year, are models of clearness. The total expenditure of the past two years amounts to £505,258, of which no less than £102,728 have been absorbed in buildings, and £68,342 in plant and machinery. Mains during 1888-89 figure for £44,307, converters for £26,632, and meters for £1,682, while the cost of the Provisional Order was close upon £4,500. The sale of current brought in £25,871; and this, together with other extraneous sources of revenue, enabled the Corporation to pay a dividend on its Preference shares and carry forward a small sum.

We gather from Patent No. 3,424 of last year some further particulars of Mr. Swinburne's device of reversing pole-pieces for obviating the necessity of changing the lead of a dynamo as the load alters. The subsidiary armature core consists of a ring of wire or discs. Each commutator connection passes only once over the outside of the core, and is either made thin where it passes through the reversing field, or is embedded within a groove milled in the core, so that the reversing pole pieces may be brought very close to the armature core. The reversing magnets are adjustable in position like the brushes, and are excited by the main current, and their influence consequently increases with the load.

In the same specification several devices are described for decreasing the excitation of the field-magnets of a synchronous alternate-current motor as the load is increased. In order to obtain self-excitation, and to prevent sparking, Mr. Swinburne proposes an exceedingly complicated method of exciting the field-magnets. This consists of two subsidiary armatures and commutators, so arranged as to give alternating currents differing in phase by a quarter of a period. These currents, when

Digitized by Google

rectified by the commutators, give a fairly constant exciting current round the field-magnets. In order still further to prevent fluctuation, it is ingeniously proposed to simply surround the field-magnets with a short-circuited coil, the induced currents in which will necessarily tend to hinder change in the number of lines of force, and will thus diminish sparking. We have recently described (*The Electrician*, March 7th, p. 452), a device due to Zipernowsky, Déri, and Bláthy for accomplishing the same object by somewhat similar means.

Dr. Moser, whose experiments on the electrical resistance of highly rarefied air we have recently described (*The Electrician*, March 14th, page 471), has been investigating whether there is any measurable difference in the specific inductive capacity of air in the various states of rarefaction he has worked with. Apparently he expected to find great changes, for his methods of measurement are not very sensitive. The differences found by Boltzmann, Ayrton, and Perry for the dielectric constants of vacuum, air, and the common gases, did not amount to more than about 6 parts in 10,000. Rarefied air would, presumably, have a specific inductive capacity intermediate between those for ordinary air and vacuum, and the variation in its amount would be far too small to be distinguished with such apparatus as Dr. Moser employed. His failure to find any alteration does not therefore prove anything.

The curious influence of magnetization on the electrical conductivity of iron, nickel, and cobalt, has recently formed the subject of a research by M. Goldhammer. Plates of the different magnetic metals were placed parallel or perpendicular to the lines of force produced by a large electro-magnet, and the resistance of them was measured by a Wheatstone Bridge. For bismuth the percentage variation was found to be proportional to the square of the magnetising force, and also to the square of the magnetisation; since, for this metal, there is a constant ratio between the two. The greatest variation took place perpendicular to the lines. For nickel and cobalt the resistance increases in the direction of the lines, and decreases in the perpendicular direction, the variation being independent of the sign of H, the magnetising force. The percentage variation tends rapidly to a maximum as H increases, and attains it sooner for cobalt than for nickel; and since the curve connecting the two is very much like the curve connecting H with the intensity of magnetisation, the author assumes that the variation, as in the case of bismuth, is proportional to the square of the magnetisation. M. Goldhammer concludes from his experiments, and from some due to M. Du Bois, that in a magnetic field the physical properties of metals undergo modifications dependent on the direction of the lines of force. If these alterations are reversed with the reversal of the lines they vary directly as the magnetic intensity, while, if they are unchanged by the reversal, they are proportional to the square of the magnetic intensity.

The opposition of the Bath Gas Company to Mr. Massingham's electric lighting scheme still continues. Not content with having induced the Board of Trade to send down Major Cardew to inspect the underground main work, and with a similar inspection by Sir F. Bramwell's assistant, Mr. G. Harris, the Gas Company now ask the Board of Trade to insert clauses in Mr. Massingham's licence which would virtually place the electric light enterprise at their mercy. As, however, the provisions usually contained in licences and orders afford ample protection to gas and water mains, it is improbable that the Board of Trade will substitute for them the one-sided clauses proposed.

Messrs. T. Commerford Martin and Joseph Wetzler, the able and well-known associate editors of the *Electrical World* of New York, have severed their connection with that journal, and now occupy similar positions on the editorial staff of the *Electrical Engineer* of New York, which will in future appear every week. The new editor of the *Electrical World* is Dr. Louis Bell, whose recent contributions to electric traction literature have been as much appreciated in this country as in the United States. Under the ægis of Dr. Bell the *Electrical World*, it may be anticipated, will continue to hold the leading position amongst American electrical journals.

Royal Institution.—The general monthly meeting of the Institution will be held on Monday, April 7th, at 5 p.m.

Strasburg.—The Town Council have granted a concession to Messrs. Schulze and Isenbeck for the erection of a central station for the supply of light and power.

The North Metropolitan Tramway Company.—This Company have obtained their Bill for the application of electric traction to the whole of their system.

St. George-the-Martyr Vestry.—At the last meeting of this vestry it was decided to assent to the Provisional Order of the London Electric Supply Corporation.

St. James' Vestry.—At the last meeting of this Vestry it was resolved to give consent to the Provisional Order of the St. James' and Pall Mall Electric Light Company.

Northampton.—The licence of the Northampton Electric Light Company having been received from the Board of Trade the Company will shortly commence to lay its mains.

Preston.—At the last meeting of the Town Council it was unanimously resolved to assent to the application by the National Electric Light Supply Company for a Provisional Order.

Treatment of Goitre by Electricity.—Dr. Marano reports the complete cure of a goitre of considerable size and of three years' duration by electricity, in the form of strong external currents and electrolysis alternately.

The Copper Market.—According to Messrs. H. Merton's statistics, the visible stocks of copper on March 31st were 91,938 tons, contrasted with 95,152 tons on February 28th last, and 124,876 tons on March 31st, 1889.

Electric Welding.—Several members of the South Staffordshire Institute of Iron and Steelworks Managers paid a visit to the Birmingham Compressed Air Company's works on Thursday last week, to witness experiments in electric welding.

Birmingham.—At the last meeting of the Town Council the General Purposes Committee were authorised to provide for the lighting of the Victoria Courts by electricity by the Birmingham Electric Supply Company, at an estimated cost not exceeding £2,000.

Post Office Telegraph Revenue.—The revenue returns to the end of the financial year ended March 31, 1890, show that the receipts from the telegraph service amounted to £2,320,000.

Digitized by Google

an increase of £240,000 over the receipts of the preceding financial year.

Aberdeen.—At the last meeting of the Gas Committee of the Town Council a communication was read from the Board of Trade to the effect that they were about to bring in a Bill vesting in the Gas Corporations the management of the electric lighting of the burghs.

The Sheffield Telephone Exchange.—Her Majesty's Treasury have given their sanction to the construction by the Postmaster-General of a special line direct from Sheffield to Manchester, for the purpose of connecting the Sheffield Telephone Exchange with that town and district.

Breslau.—The town authorities have voted 1,000,000 marks (£50,000) and have given the contract for installing 10,000 16-candle-power lights to Messrs. Siemens and Halske. The work is to be completed by March 1, 1891, and the town will work the installation when it is completed.

Berlin.—Negotiations are pending between the Directors of the Grosse Berliner Pferdebahn-Gesellschaft and the Berliner Elektricitäts-Werken, with a view to the introduction of electric traction on their lines. It is said that the Friedrichstrasse-Kreuzberg line will be the first to be tried.

Institution of Electrical Engineers.—At the next meeting of the Institution, on Thursday, April 10th, the following Papers will be read:—"On Signalling across Rivers in India," by W. T. Melhuish, member. "The Diathermancy of Air in relation to the Efficiency of Incandescent Lamps," by Frederick Higgins, member.

Verona.—According to *l'Elettricita*, the people of Verona are greatly in favour of the electrical scheme of Signor Enrico Carlo, who proposes to obtain the power necessary for electric lighting of the town from the River Adda, near Lecco, a distance of about 100 miles. The power available is estimated at between 7,000 and 11,000 horse-power.

Electric Traction at Liverpool. — General Hutchinson, Inspector to the Board of Trade, last week inspected and approved the car which the Electric Traction Company are about to run for experimental purposes on the Liverpool United Tramways. To meet the heavy gradients on this line, a heavier motor will be used, and both axles will be operated.

Bolton.—In reply to 1,178 circulars issued by the Corporation in connection with the question of electric lighting, 449 replies have been received: 45 only desire the electric light, but they include the large firm of Messrs. Musgrave and Sons; 24 wish for it if the price is the same as gas; 56 are uncertain by reason of the cost; doubtful, 30; and absolute negative, 314.

The Telephone at Bakewell (Derby).—Something unique may be seen in Bakewell (Derby), where some months ago the Sheffield Telephone Exchange Company extended their system by opening Exchanges in Baston and Bakewell. On Thursday last the National Telephone Company made a formal opening of a rival Exchange; and, strange to say, the switchboards of both companies may be seen installed in the same room.

Académie des Sciences.—In connection with the recent election of Lord Rayleigh as correspondent to the Physical Section of the Académie des Sciences, *La Lumière Electrique* points out that Lord Brougham, who was elected correspondent to the Section of Moral and Political Science in 1833, is the only other member of the House of Lords who has been connected in this way with the Institut de France.

Lambeth Vestry.—At a meeting of this Vestry on Thursday evening last week, it was agreed that consent should be given to the application of the House-to-House Electric Light Supply Company for a Provisional Order to extend over the whole parish, with the exception of two small areas, which have already been allotted to the London Electric Supply Corporation and the Electric Installation and Maintenance Company.

Leeds Association of Foremen Engineers and Draughtsmen.—The ordinary monthly meeting of this association was held on Thursday evening last, in the Physics Lecture Theatre of the Yorkshire College, Leeds, when Dr. W. Stroud, professor of physics at the College, gave a most interesting lecture on "Springs." The lecture was well illustrated by a large number of experiments, electrical and mechanical, and by lime-light views.

Magnet Steel.—The following testimonial, received from Prof. Perry by Messrs. Jowitt and Sons, of Sheffield, is of interest in view of the statements recently made by Mr. Preece with regard to the deterioration of magnet steel. Prof. Perry writes:—"I obtain an average *permanent* induction of 12,600 in your magnet steel. So far as I know, this is a much better result than has been obtained from any other steel. I use the steel in a glass-hard condition."

L'Elettricita.—The editor of *L'Elettricita*, which is published at Milan, would be glad to receive answers to the two following questions, from all competent electricians; these answers will be published in an early issue of our contemporary. 1. What has been the most important electrical invention, discovery, or investigation of the past year? 2. What application of electricity, already known, will make the greatest progress during the present year?

Altona.—From the *Elektrotechnische Echo* we learn that the municipal authorities of this town have given the contract for building a central station to Messrs. Schuckert and Co. The town retains the right to purchase the whole plant either on completion or at the expiration of certain stated periods. The station is designed for 10,000 glow lamps; but the plant for 5,000 only will be put down at first. The work is to be completed by October 1, 1891.

The London Chamber of Commerce.—At the eighth annual general meeting of this Chamber, held on Monday, Sir John Lubbock, in moving the adoption of the report, expressed congratulation on the continued progress of the institution. The number of new members elected during the past year had been 470, which was more than 100 above the average, the total number of members now exceeding 3,000. There were 24 trade sections, five having been added during the year, and others were in course of formation.

Berlin.—Mr. J. S. Biggs, vice-president of the Edison Lighting Company of New York, and Mr. C. L. Edgar, manager of the Edison Lighting Company of Boston, have been sent over to study the Berlin central stations. Both gentlemen have expressed their satisfaction with what they have seen. The *Elektrotechnische Zeitschrift* is of opinion that "the fact that the inventor of the incandescent lamp first comes himself, and then sends his two foremost engineers to study the Berlin central stations, ought to fill the German electrical world with pride."

The Telegraph in Burmah.—During the past year 3,117 miles of wire were added to the telegraph system of Upper and Lower Burmah. Permanent lines have been constructed from Sagaing to Myinma 32 miles in length, Meiktella to Meiktella Road 13 miles, Kindat to Tamu 48¼ miles, Bhamo to Mogaung 88⅓ miles. The number of messages decreased by 15·4 per cent., and their value by 44·4, as compared with the average of previous years. The reduction is accounted for by decrease in State traffic. In Upper Burmah the number of messages wired is given as 370,964, as compared with 564,066 in the previous year.

The Accumulator Cars on the Madeleine-Levallois Line.—The accumulator cars now being tried on the Madeleine-Levallois line of the Compagnie des Tramways Nord of Paris are four in number. The current is obtained from 108 cells of the Société Française d'Accumulateurs Électriques. The cells are placed on shelves arranged at the angles of the cars, and weigh 1,620 kilogrammes (1½ tons). The motor is of the Siemens type, and runs normally at 1,000 revolutions, the speed being reduced at the car axle in the ratio of 26 to 1 by endless cord gearing. Variations of speed are effected by altering the grouping of the cells. The cars, which carry 50 passengers, weigh 3,500 kilogrammes (3½ tons). The normal rate of travel is 11 kilometres per hour, at which speed the motor requires 200 volts and 16 amperes. The Société Française estimate the cost of accumulator traction at 30 centimes per car kilometre.

The Stepanoff Electric Bleaching Process.—In the method of electric bleaching devised by M. Stepanoff, common sea salt is employed instead of chloride of magnesium, as in the Hermite process. A solution of sea salt is pumped into an "electrolyser," having lead and platinum electrodes, and is there submitted to electrolytic action; after which the electrolysed solution is pumped into the bleaching tanks. With his present apparatus M. Stepanoff uses 40 amperes and 45 volts, and is able to furnish 300 litres (66 gallons) of chloruretted solution per hour. Although matters may be so arranged that a 1·6 per cent. solution can be obtained, M. Stepanoff does not, as a rule, employ a solution containing more than ·7 per cent. of chlorine. The substitution of lead for zinc electrodes in the "electrolysers" is claimed as an improvement.

A Recipe for Making Battery Boxes Watertight.—It is often advantageous to employ wooden vessels for battery and electro-plating purposes in place of the jars in ordinary use. It is, however, necessary that they should be perfectly watertight and unacted on by the electrolyte. M. Fontaine Atgier gives the following recipe for this purpose:—Coat the interior of the vessels with a hot liquid mixture of paraffin and gutta-percha, obtaining the requisite degree of polish by passing a hot iron over it after application. If it is desired to avoid applying the coating in a hot state, make a mixture composed of sulphate of carbon or of benzine, and gutta-percha and bitumen; the compound being applied with a brush. Care must in this case be taken to work at some distance away from any arc lamp or other powerful source of light.

The Edinburgh Exhibition.—By the invitation of Sir George Hayter Chubb the London Committee of the Edinburgh Exhibition and a number of gentlemen interested in its success were entertained to dinner in the Hôtel Métropole, last week. Amongst those present were the Secretary for Scotland, Lord Colville of Culross, the Lord Mayor of London, Sir Thomas Clark, chairman of Executive Council; Sir John Fowler, Sir Douglas Galton, Sir John Pender, K.C.M.G.; Sir Frederick Abel, C.B.; Sir V. Kennett Barrington, Sir James N. Douglas, C.E.; Prof. George Forbes, F.R.S.; and Mr. W. H. Preece.—Messrs. F. B. Seath and Co., of Glasgow, are making good progress with the electric launches to be run on the canal during the Exhibition. Each boat will carry 30 or 40 passengers, landing them most conveniently at the entrance to the building. It is also intended to run pleasure trips during the season.

Manila Paper Insulation for Telephone Cables.—The electricians of the American Bell Telephone Company have lately undertaken some experiments with a new type of telephone cable insulated with Manila paper. Other things being equal, the substitution of Manila paper for cotton diminishes the specific inductive capacity of a cable by 30 per cent.; and since the cost of insulating a cable in this way is very little more than the cost of insulating it in the ordinary manner, it may be anticipated that Manila-paper-insulated telephone cables will come into general use in the United States for underground work, should the experiments at present going on prove them to be satisfactory in other respects. According to Mr. Barrett, Manila paper is less hygroscopic than cotton. The paper can be wrapped very tightly round the wires, and the insulated covering presents a shiny, smooth, flexible surface.

The Langhans Incandescent Lamp.—The main characteristics of the Langhans incandescent lamp are the low vacuum it requires and the employment of a metallic filament coated with silicium. As a vacuum corresponding to about 1 millimetre is all that is necessary, it can be produced by a mechanical vacuum pump specially constructed for the purpose by Mr. Langhans. The several processes employed in coating the filaments with silicium are simple, inexpensive, and permit of a high degree of accuracy in predetermining the voltage. The life of the Langhans filament at 2·75 watts per candle-power is said to be equal to that of the best carbon makes. Ordinary carbon filaments can be coated with silicium by the Langhans process, and it is claimed that they then require less current in order to give the same amount of light, and can be made to work satisfactorily in the same low vacuum as the Langhans filament proper.

The Marx Accumulator.—The principle of an accumulator recently brought out by Herr Marx, of Berlin, is briefly as follows:—If an electric current is passed through a dilute solution of hydrochloric acid and perchloride of iron, in which are immersed carbon electrodes, the following reaction takes place:—$2\,FeCl_2 + 2HCP = Fe_2Cl_6 + H_2$. If, then, a carbon and an iron electrode are plunged into the electrolyte the following reverse reaction, giving rise to a powerful current, takes place, $Fe_2Cl_6 + H_2O = 2\,FeCl_2 + 2\,HCl + O$. The perchloride may be prepared by taking 450 parts of protochloride of iron, 900 of water, and 500 of hydrochloric acid (25 per cent.). The perchloride can then be concentrated, or even crystallised by evaporation, and in that state may be carried about. The carbon electrode in the second case must be very porous, or pierced with numerous holes. The iron electrodes are not consumed; on the contrary, an open circuit iron is deposited on them, so that they must be removed when the battery is not at work.

Alloys for Standard Resistances.—At a recent meeting of the Berlin Physical Society, Dr. Feussner, in describing the methods employed at the Government Physico-technical Institute for the measurement of electrical resistances, remarked that German silver wires had shown themselves unsuited for standard resistances, since their resistance increases regularly with lapse of time. On this account an alloy of copper and nickel was examined which is known commercially as "patent nickel." Wires made of this alloy possess a very low temperature-coefficient, and were found to be almost absolutely constant after being heated to 100° C. Several other alloys were also tried, as, for instance, various combinations of copper and manganese. Dr. Feussner stated that up to 30 per cent. of manganese—above which amount it was not possible to draw a wire in this alloy—they had yielded a negative temperature-coefficient. When the alloy contained only a small percentage of manganese, the coefficient was very small, so that such wires would be suitable for the construction of standard coils.

The Distant Operation of Water Gates by Electricity.—The Elektron Manufacturing Company, of Brooklyn, have recently built two Perret motors for the purpose of operating some hydraulic gates at a distance of several miles. One motor is to be used at Marion, O., at a distance of three miles, and the other to be used at Decatur, Ala., at a distance of a mile or more from the operator. The dynamo used in each case is a small constant-current machine. By changing the direction of the current at the dynamos, the motors, which are series-wound, are run in either direction at will. The reversal of motion is effected by an ingenious automatic device, invented by Mr. Frank A. Perret, the electrician of the Elektron Manufacturing Company, which is attached to the motor and keeps the polarity of the fields unchanged regardless of change in direction of the current on the line, while the current in the armature is reversed with each change in the main current. The water gates are thus controlled and placed in any desired position at the will of the operator miles away, by simply throwing a switch lever.

The Electric Welding of Wire Cables.—Electric-welding machines are being erected by the Trenton Iron Company (N.J.) for the purpose of welding cables by the Thomson electric welding process. The cables to be welded are 1¼in. in diameter, and are composed of four successive layers of wires, with a single fine wire core. Experiments made with a view to determine the tensile strength of the welds produced in this manner show that the maximum tensile strength of a cable was 67,000lb. per square inch before annealing, and about 50,500lb. after heating to a temperature slightly below a welding heat, and then allowing the metal to cool slowly, and that the tensile strength of the welded cable averages over 50,000lb., some specimens resisting a stress of as much as 53,000 or 54,000lb. per square inch. The ratio of elastic limit to ultimate tensile strength is about the same in unwelded as in welded specimens. Severe bending and twisting tests give equally good results, it being possible to bend the cable at the weld backwards and forwards many times through an angle of 180deg.

Telegraphing the Progress of the Boat Race.—A successful attempt was made this year for the first time by the Exchange Telegraph Company to signal to their subscribers the progress of the Oxford and Cambridge boat race. Those connected with this Company's system were thus made acquainted with the time of arrival of the competing crews at various points of the course, and the relative positions which they occupied at intervals of a few minutes, the result being made known at 800 places in London alone a few seconds after the termination of the race. Not only were the London clubs and others thus supplied with an account of the race, unattainable on the course itself, but newspapers in the country were enabled to go to press with a complete and accurate description much earlier than has hitherto been possible. An example of the promptitude of delivery of this news was furnished by the *Manchester Evening News*, which was being sold in the streets of Manchester at 5.20 p.m., with the description of the race from start to finish, this being only 14 minutes after the conclusion of the race at Mortlake.

The Municipal Tariff at the Halles Centrales.—The *Bulletin International de l'Electricité* has discovered some curious anomalies in the tariff drawn up by the Director of the Paris Municipal Central Lighting Station at the Halles Centrales. The energy consumed is charged for at the rate of 15 centimes per 100 watt-hours. Any consumer, however, whose lamps have all burnt on an average 150 hours per month, has 10 per cent. taken off his monthly bill; if the average attains 180 hours a 20 per cent. reduction is made; and 30 per cent. is deducted if the lamps have all burnt 200 hours during the month. The result of these liberal discounts, in the case, for instance, of an installation of ten 16-candle-power lights, is somewhat startling:—If the ten lamps are used 149 hours per month, the bill will amount in round numbers to 143fr.; if used 150 hours, the charge will only be 129fr. 60c.; while for ten lamps burning 181 and 201 hours per month, the charges will be respectively 139fr. and 135fr. An increase of over 30 per cent. in the consumption may thus result in a 5½ per cent. diminution of the consumer's bill.

The Tatlow Battery.—This battery is composed of a zinc and peroxide of lead couple in dilute sulphuric acid. The peroxide of lead is obtained as follows: A lead foundation plate is filled in with a paste of lead oxides, made of red lead and sulphuric acid, or litharge and lead acetate solution—a plate, in fact, similar to an ordinary storage battery plate. When the paste has set hard the plate is placed in a solution of chloride of lime, whereby the salts and oxides of lead are gradually oxidised to lead peroxide, the rapidity of the reaction depending on the temperature and degree of concentration of the solution. It is absolutely necessary that there should be enough free lime present to keep the liquid alkaline. When completely oxidised the plate is taken out of the solution, well washed, and is ready for use in the cell, giving with zinc and dilute sulphuric acid an E.M.F. of 2 to 2·3 volts. After the plate has ceased to be active it is to be washed and returned to the hypochlorite solution. The same plate thus serves again and again, acting as a carrier of oxygen between the hypochlorite and the zinc. The reaction in the hypochlorite solution possibly involves the formation of a lead or lead-calcium hypochlorite during the process.

The Agitation amongst the Telegraph Clerks.—The Postmaster-General received on Monday a small deputation representing the telegraphists previously employed by the Submarine Telegraph Company, and who are now in Government employ. These men, who share with the other telegraphists various grievances, have also their own special grievances. They complained that they were unfairly classified, that their superior work was not taken in consideration, and that they had been deprived of the benefits of a generous scheme of life insurance which they enjoyed under the old Submarine Company. They also asserted that, although the Continental service necessitated a knowledge of foreign languages on the part of the telegraphists, no allowance was made for such special acquirements. The Postmaster-General, having listened to statements in support of the memorial, said that the whole subject was under the consideration of the Department, and the deputation withdrew.—The following is the resolution which Lord Compton will move in the House of Commons on Tuesday, the 15th, with reference to the telegraphists, "That, in the opinion of this House, the present position of telegraphists in London and elsewhere is unsatisfactory, and their just grievances require redress."

Frankfort International Electro-Technical Exhibition, 1891.—We have received from the Executive Committee of this Exhibition particulars with regard to charges for space, forms of application, &c. The Exhibition will be opened on May 15, 1891, and will close on October 15th. The exhibits will be classified under twelve sections:—I. Motors for electro-technical purposes. II. Generation of electricity. III. Conductors and auxiliary apparatus. IV. Accumulators and switches. V. Transmission of electric power. VI. Electric lighting. VII. Telegraphic and telephonic apparatus. VIII. Electric signalling. IX. Electro metallurgy and electrolysis. X. Measuring instruments. XI. Medical electricity. XII. Electro-technical literature. Applications for space must be sent to the Executive Committee before July 1st, 1890. The delivery of exhibits which will require some time to erect may commence on March 15, 1891, and must be completed on April 15th. Other exhibits may be sent in up to May 1st. The charges for space are as follows:—A. Main building, 15 marks the square metre (about 1s. 5d. the square foot). B. Semi-covered space, 10 marks the square metre. C. Open air, 2 marks the square metre. The cost of insurance is to be paid by the exhibitors. The charge for power will be 1½d. per horse-power hour, 3 horse-power being the minimum.

The Measurement of Electro-Magnetic Radiation.—At the last meeting of the Physical Society of Berlin, Dr. Rubens spoke on the employment of the bolometer for observing the electrical radiations of Hertz as carried out by himself and Dr. Ritter. Up to the present it had not been found possible to measure the intensity of the radiation, owing to the extraordinarily minute amplitude of the oscillations; but the speaker had been able to carry out the determination by means of a special form of bolometer. It consists essentially of an accurately balanced primary Wheatstone bridge, two of whose arms are again converted into secondary Wheatstone bridges. If a current passes through one of them its resistance is altered by the rise of temperature, and the galvanometer gives a proportionate throw. A similar effect is produced by a wave of electrical radiation, and hence its amplitude can be measured by this bolometer when once it has been calibrated. When experimenting with the polarising wire-grating it was found that there is a constant relationship between the intensity of the rays which pass the grating and the angle of inclination of the wires to the plane of oscillation of the rays. It was further observed that the energy which does not pass the grating is reflected, and to the extent of 98 per cent., when the wires are at right-angles to the plane of oscillation.

Specific Inductive Capacity of Rarefied Air.—In a recent Paper (see *The Electrician*, March 14, 1890), Dr. James Moser has shown that, while air rarefied to the extent common in Geissler tubes, is a conductor, a high vacuum is really an insulator. It was of interest to determine the specific inductive capacity of air in these two states, and with this view a Leyden jar was constructed with air as the dielectric. A Geissler pump was placed in communication with the condenser, and also with Dr. Moser's double vacuum tube already described. The former was used to rarefy the air, and the latter, when excited by an induction coil, to indicate by its appearance the state of rarefaction. Both were disconnected from the condenser when the capacity measurements were taken. A Mascart-Carpentier electrometer was used, whose capacity was comparable with that of the air condenser. The quadrants were charged with a Latimer Clark's cell, and the needle by communication with the air condenser, which had been previously charged by means of a Zamboni pile. The deflections produced should vary with the specific inductive capacity of the rarefied air, since the potential of the Leyden jar must fall on being connected with the needle by an amount depending on the ratio of the two capacities. The results obtained by Dr. Moser were, however, negative, no certain variation in the deflection being established.

MAGNETISM IN IRON AND OTHER METALS.*—XII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 518.*)

§ 57. **Magnetic Force in Rings.**—Though the magnetising solenoid is uniformly wound over the whole ring, so that its effect at any one cross-section is the same as at any other, the magnetic force is not quite uniform throughout. It is strongest at the inner side—the shortest length—of the ring, and decreases towards the outer side in proportion as the radius of the ring increases. This is because the number of turns per centimetre is greatest at the inner side and least at the other. Let N be the whole number of turns of the magnetising solenoid, the number per centimetre at any radius r is $\frac{N}{2\pi r}$ and the magnetic force is $\frac{4\pi CN}{2\pi r}$, or $\frac{2CN}{r}$. Thus the magnetic force varies from $\frac{2CN}{r_1}$ at the inside to $\frac{2CN}{r_2}$ at the outside (Fig. 24). So far as it goes, this is a drawback to the use of ring-shaped specimens.

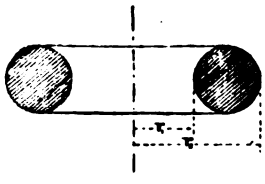

FIG. 24.

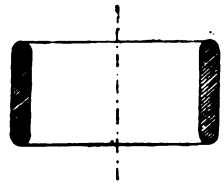

FIG. 25.

To prevent this objection from having much weight the thickness of the ring should be small compared with its radius. The form shown in Fig. 25 allows a small ring to be used without excessive variation of magnetic force over the section within, and without unduly reducing the sectional area.

In dealing with weak magnetic forces it is desirable to place the ring in such a position that the earth's magnetic field does not affect the uniformity of its magnetisation, namely, in the plane perpendicular to the direction of the lines of terrestrial force. For the sake of homogeneity in the metal itself, a ring turned out of a solid block is to be preferred to one that is forged from a bar.

§ 58. **Bar and Yoke.**—The condition of endlessness, which is realised perfectly in a ring of uniform section, uniformly wound (or, rather, is realised as perfectly as the imperfect homogeneity of the metal will allow), can be approximated to, even

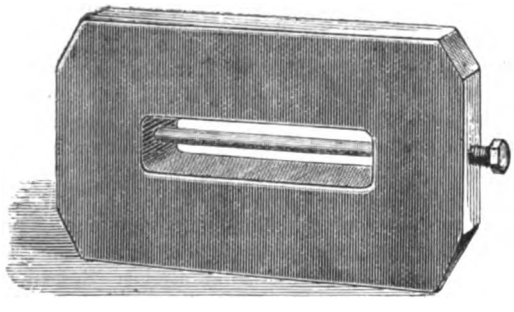

FIG. 26.—Yoke for the Ballistic Tests of Bars.

when the sample has the form of a short bar, by a very interesting and useful method, invented by Hopkinson.† Let the ends of the bar be sunk in holes in a massive yoke (Fig. 26) which has an area of cross-section many times greater than that of the bar, and is made of the most permeable material available, namely, soft annealed wrought iron. The yoke is so much better a conductor of lines of magnetic induction that the lines which proceed from either end of the bar nearly all pass back through it to the other end, instead of escaping into surrounding space. This closing of the magnetic circuit through the yoke prevents the bar from exercising almost any self-demagnetising force upon itself; and if the bar is wound with a magnetising solenoid throughout its whole clear length within the yoke,* the magnetic force actually operative on it is only a very little less than the whole force due to the solenoid.

The amount of the difference will be more easily discussed when we come, later, to speak of the magnetic circuit as a whole, and the relation of the induction in it to the whole number of ampere-turns in the magnetising coil. Meanwhile, it may suffice to say that the magnetism of the bar and yoke reacts to a small extent on the magnetic force, reducing it by amounts which are proportional, or nearly so, to the magnetisation. The effect is like that which has already been described as occurring in a long rod or long ellipsoid, not so extremely long as to be virtually endless, and the curve of magnetisation is consequently sheared over (§ 48): the apparent susceptibility and the residual magnetism are reduced. This makes the method of the yoke unsuitable for accurate determination of the susceptibility and retentiveness of a very susceptible metal, like soft wrought iron; but there is no material error in the case of hard iron or steel.

The ends of the bar should be sunk for a considerable distance into the yoke, and should fit in the holes without shake, for if there is any appreciable clearance its effect in causing self-demagnetising force may be considerable.

§ 59. **Hopkinson's Application of the Bar and Yoke.**—In applying the ballistic method to a bar in a yoke we may, of course,

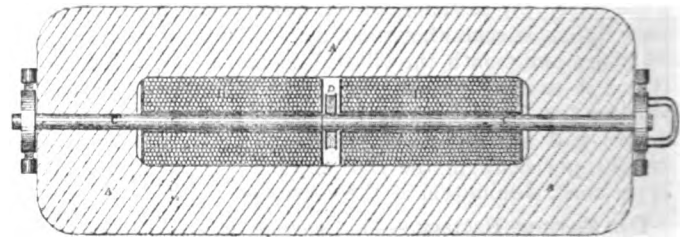

FIG. 27.

proceed by steps or by reversals, as with a ring. In Hopkinson's original use of the yoke, however, a different procedure was followed. The bar was made in two parts, C and C′ (Fig. 27), which abutted against one another near the middle, where the secondary coil D was slipped on, in a space between two halves of the magnetising solenoid B B. A clutch fixed on the projecting end of the rod C enabled it to be suddenly drawn away from C′ sufficiently to allow D (which was pulled sideways by a spring) to leap out of the field. This gave a ballistic throw which measured the actual magnetic state of the bar at the moment when C was drawn out. The plane of section between C and C′ is a rather objectionable feature in this arrangement: for, as will be shown later, its influence on the general permeability of the bar is by no means immaterial, even when the abutting surfaces are accurately faced.

§ 60. **Double Bars and Yokes.**—Figure 28 illustrates an arrangement which should serve well when two equal bars of

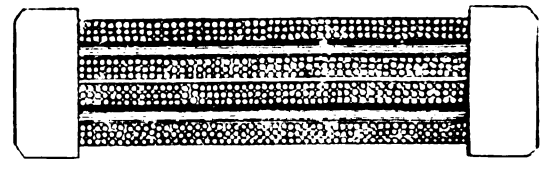

FIG. 28.

the material to be tested are available. The bars should be of considerable length—twenty or more times the diameter, and the yoke should be short and thick. Equal magnetising solenoids are wound over each, and are connected to give opposite directions

* All rights are reserved.

* In the figure the bar is shown in its place, but the magnetising solenoid and the induction coil are omitted.

Digitized by Google

of magnetisation. The secondary coil is preferably distributed over the middle region of both bars. If it is wished to measure the actual magnetic state at any time, one of the yokes may be arranged so that on pulling it away it brings the secondary coils with it.

(To be continued.)

ELECTRIC ARC LIGHT CARBONS.

BY O. G. PRITCHARD.

(Continued from page 494.)

Having described in my previous Paper the graphitic material or compound used in carbon candle-making, the manipulation required in the preparation of the stuff, also the way in which the granular condition is acquired, and which experience shows is essential to the production of a good carbon, I now proceed to explain the method of preparation of the saccharine matter employed in combining the material to form the paste, or pugged stuff possessing the special properties requisite. All materials hitherto experimented upon and used to combine the powdered graphite, such as tar, oils, gums, hydro-carbons, rosin oil, &c., swell the carbons, after being subjected to a drying heat, inducing porosity; and no available after-process is satisfactory. Saturation with carbonised sugar fills the pores, but leads to much waste of time and enhanced expense, both of material and labour. Wellnigh two of the first years which I devoted to this subject were spent in efforts to overcome this difficulty, efforts not made in vain, since not only is the perfect drying of the carbon without swelling now a "*fait accompli*;" but also the valuable property of contracting under great heat has been realised, so much so, indeed, that allowance has now to be made in the gauge of the die, which, to allow for this contraction, requires to be increased $\frac{2}{16}$th of a millimetre upon a 10-millimetre carbon. Prolongation and intensity of firing increase the contraction. The high conductivity possessed by graphite is, no doubt, due to its peculiar dense condition; but to impart this quality of density we shall have to wait until Nature invites us to work in her own laboratory.

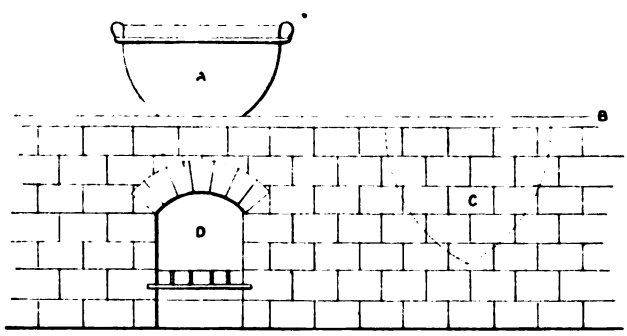

FIG. 1.

The material I use to incorporate with the prepared graphite powder is the best crystallised lump sugar. Crystallised Demerara might do as well, but the difference in cost is so slight that I prefer to adhere to the former; and, therefore, would cite "Tate's cubes" as the standard. I would urge that no attempts be made to cheapen this part of the process. Molasses and treacle are impure, containing, besides sugar, acetate and sulphate of potassa, chloride of potassium, phosphate of lime and copper, mucilaginous and nitrogenous matters, silica, water, and glucose.

Take, say, 20lb. of Tate's cubes, put them into a boiler large enough to hold four times the quantity, at least; place the boiler on a moderate fire, preferably made of small broken coke, and allow the sugar to melt gradually, without burning, until it partially carbonises. Careful stirring and watching must be exercised, and it must never be at any moment left, or the sugar is certain to boil over, catch fire, and be wasted. To avoid these *contretemps*, a low range of firebricks may be built (see Fig. 1), on the top of which bars, B, of iron are fixed, immediately over the fire, and extending over a sunk pan, C. The boiler A is free to slide upon the bars, so that in the event of a sudden rise it can be pushed over the sunk pan, and any overflow of the contents be recovered without loss.

I have signally failed in the use of beet sugar. When converted into caramel, it decidedly loses the adhesive, sticky property belonging to the cane sugar. Sugar heated to 400° F. loses two equivalents of water, becomes brown, cannot be re-crystallised, and is then known as caramel. At 410° F., the third equivalent of water is set free, and complete carbonisation commences. In this state the spec. grav. is 1·594. Sugar at this stage ceases to rise in the boiler. By observation alone can the point at which the caramel is in the exact state required be determined. As a guide, however, it may be stated that the process is well-nigh completed when the sugar ceases to rise in the boiler; but make sure that this is not owing to the lowering of the fire. Small volcanic eruptions covering the surface, bursting and emitting vapours which are caused by the third equivalent of water becoming free, is another sign. If any smoke accompanies the vapour, the operation is certainly complete. The process had always better be carried a little too far than not far enough. In the first case, the caramel is only slightly less adhesive, leading to extra pugging; but in the second case the carbons will suffer, and this will not be ascertained until the carbons have been made and placed in the drying-room. To determine the right moment for closing the operation above described, needs practice, the appearances shown whilst boiling depending much upon the state of the fire, and being sometimes misleading and puzzling to any but the expert. When the boiler has been duly removed from the fire, add gradually *small* quantities of hot water. Adding cold water in bulk is an experiment not likely to be repeated more than once. Stir well while adding the water, and let this be only sufficient to keep the caramel liquid when cold. When required for use this stock must be diluted with cold water to about the consistency of golden syrup one part, water two parts, possessing a slight stickiness when rubbed between the fingers.

The carbon powder may now be taken out of the storage bin, in quantity sufficient for a pugging, with a pug-mill 6ft. 6in. over all, with rollers 18cwt. each. A 10 horse-power engine is sufficient to drive the mill and the press. About three tin buckets, holding about 20lb. each of the powder, may be taken as a charge, and this weight of material will suffice to form 1,000 10-millimetre carbons. Pug this stuff, adding sufficient of the liquid caramel to form a paste; when pugged, clear out the mill, and transfer the paste to a covered bin, or keep it in the buckets, marking the date when first pugged on the buckets. Continue making these batches, repugging every day until ready for the press. This pug-mill should be kept solely for the purpose of pugging, and not grinding, as the pan could not be so thoroughly cleaned as to avoid the risk of leaving some small fragments of material, which would find their way into the carbon rods, tend to divert the current when used, and give rise to complaints.

A portion of each day may be employed in pugging new stuff, previous puggings must also have the process repeated daily, each day's batches being kept separate. Three or four days, depending somewhat on the temperature, will bring the stuff to a proper condition for forming into carbons. The paste may be advanced, if required, by placing it in a warm room. By squeezing the paste in the hand the expert can tell the atmospheric pressure requisite to drive it through the press within some 10 atmospheres. This pressure must not be under 120 atmospheres for a 10-millimetre carbon. This same paste, however, that requires 120 atmospheres for 10 millimetres, would in the case of 14 millimetres pass through at 90 to 100 atmospheres. The first few carbons issuing from the press will be no guide, as the pressure will increase until the carbon in the cylinder becomes well compacted; this will occur whenever the cylinder has been emptied for the purpose of changing the die or altering the coring needle. If the cylinder has been charged, the pressure right, and the carbons issuing from the die, the carbons will require cutting to normal lengths. For this purpose I use a small instrument, which answers the

Digitized by Google

purpose, and cuts off the carbons to a standard length as they issue from the press. It is made of tin, about three-quarters of an inch wide, bent at right angles at D (Fig. 2). The carbon rod A, shown in section, lies in the grooved top B, the thumb slightly pressing the carbon, while the spring-back cutting part is pressed forward with the fingers; this closes over the groove B, separating the carbon at the normal length.

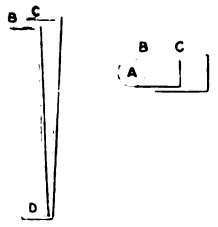

Fig. 2.

As the carbons are thus cut off they must be laid in grooved plates, prepared by a machine (Fig. 3) constructed for the purpose, consisting of a cast-iron frame, with grooved dies; the lower die B is fixed to the frame EE, whilst the upper die A slides vertically in the frame. This upper die is actuated by a lever handle C, working eccentric chuck-pieces, fastened to each end of the bar, actuated by the lever, and turned by the handle so as by its action to bring the dies in contact. The sheet tin, being laid upon the guide-plate G, is pushed forward through

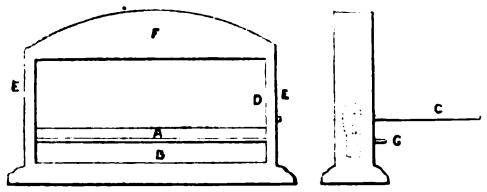

Fig. 3.

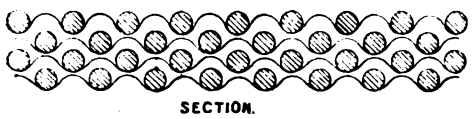

Fig. 4.

the open dies, and takes the form of the grooves upon lowering the arm; an iron rod at the back also guides the plate in its passage, keeping the grooved plate straight. These dies may be taken out of the frame to give place to others suitable for carbons of other gauge. These grooved plates (Fig. 4) upon which the carbons are carefully laid as soon as they issue from the press, are so constructed and figured that the carbon rods are perfectly protected from the superimposed plates pressing upon them, the plates resting upon each other, the carbons

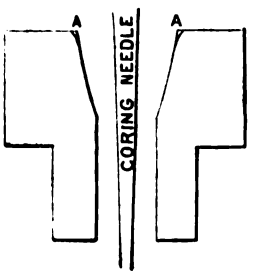

Fig. 5.

being protected withint he grooves; thus a dozen plates filled with carbons may be safely piled one upon another before leaving the pressman. These plates should be made two inches longer than the carbons, of the best charcoal tin, and rather stout. In these corrugated plates the carbons should remain until removed for firing in the kiln, tin being a good conductor of heat, accelerating the process of drying. When the pressman has filled a dozen of these plates they may be placed on a rack in the press-room. Here they may remain until the evening, when they may be transferred to the first drying-room.

I must here describe a fault which may arise by the time this stage is reached. The carbon rods leave the press, to all appearance perfect; half-an-hour afterwards every carbon is lined with fine fissures at right angles to the length of the carbon rod, increasing in size and depth as they dry. The fault arises from the die. I had occasion at the time I first noticed this defect to renew my stock of dies, and

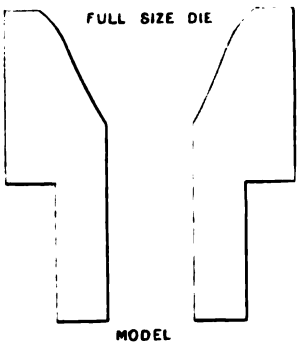

Fig. 6.

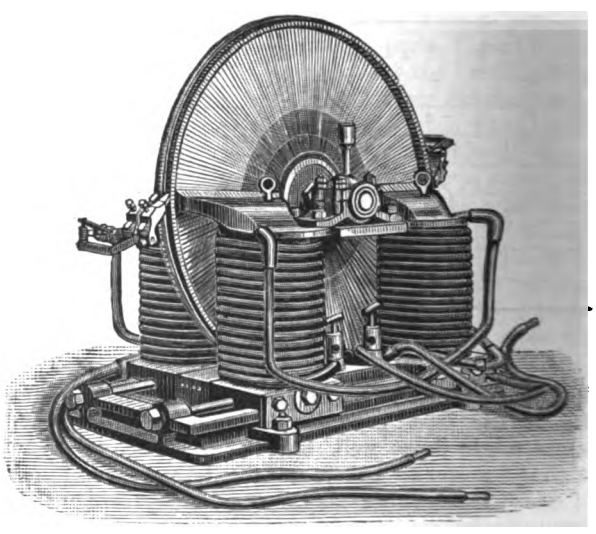
gave a model to an experienced workman, who furnished me with duplicates, apparently in every respect similar to model, only slightly reduced in gauge. No eye-measurement could detect any difference; but on slightly filing off the shoulder at A (Fig. 5) the difficulty disappeared, and the carbons were perfectly freed from this blemish. A model die for a 10-millimetre carbon is shown in Fig. 6.

(To be continued.)

THE POLECHKO DISC DYNAMO.*

The following details relating to this dynamo were given by its designer at the recent Congress of Russian naturalists. The inventor seems to have attempted to design a commercial dynamo on the principle of Barlow's wheel. The armature of M. Polechko's dynamo (*see* figure) consists of a single piece of metal, one metre in



Polechko Disc Dynamo.

diameter, insulated from the shaft, and cut radially into 350 segments, separated from one another by fibre to within 13 centimetres of the shaft. The periphery of the disc is furnished with a steel rim, insulated from the disc itself, and widened out on either side of the disc, so as to serve as a collector.

In a machine of this character, the E.M.F. which can be usefully induced along a segment may be calculated as follows:—Let a_1 be the radius of the disc, and a the radius of the centre portion. Then the length of the conductor l within the magnetic field is

$$l = a_1 - a.$$

* From *La Lumière Électrique.*

Digitized by Google

Let n = the number of revolutions per second. Then v, the mean linear velocity of each radial portion of the disc, is

$$v = 2\pi \frac{a_1 + a}{2} n.$$

Calling H the intensity of the magnetic field in C.-G.-S. units, the E.M.F. in volts induced in each radial segment is as follows :—

$$e = \frac{n\,H\,v\,l}{10^8} = \frac{n\,H}{10^8}\pi(a_1 + a)(a_1 - a) = \frac{n\,H}{10^8}\pi(a_1^2 - a^2).$$

The total E.M.F. induced in two opposite segments is—

$$E = \frac{2\,n\,H\,v\,l}{10^8} = \frac{2\,n\,H}{10^8}\pi\,(a_1^2 - a^2) = \frac{2\,n\,H}{10^8}S,$$

S being equal to $\pi(a_1^2 - a^2)$—that is to say, the active surface of the disc.

According to this formula, and with the dimensions of the first machine constructed by M. Polechko, we find that at a speed of 1,600 per minute the dynamo could develop 50 volts when H = 12,600. As a matter of fact, in the first machine, H was only equal to 6,500, and the machine gave 25 volts and 2,000 amperes at 1,500 revolutions per minute, its weight being 1,140 kilogrammes (about 22 cwt.). At the present moment M. Polechko is constructing a modified machine, having almost the same dimensions as the first, and it is possible that these dynamos, of solid construction, small weight, and extreme simplicity, may prove useful in electrolysis, electro-metallurgy, and even electric lighting.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 21st inst., Mr. H. Tomlinson, F.R.S., read a Paper on

"The Villari Critical Points of Nickel and Iron."

The author began by recalling the fact that Villari was the first to discover that longitudinal traction increased the magnetic permeability of iron for values of the magnetising force below a certain critical point, and diminished it for higher values. This critical value of the magnetising force, for which longitudinal traction had no effect, was therefore known as the Villari critical point. As far as he was aware no observer had succeeded in finding a similar critical point for nickel, and he understood that Prof. J. J. Thomson had theoretically arrived at the conclusion that no such point could exist. Having regard, however, to the temporary magnetisation only, the author stated that he had succeeded in finding a Villari critical point for nickel. The ballistic method of observation described in the *Philosophical Magazine*, Vol. XXV., 1888, p. 372, was employed in the experiment described in the present Paper. The nickel wire contained about 98 per cent. of pure nickel, and only 0·7 per cent. of iron, while the iron wire he believed to be nearly pure, judging from its low specific resistance. In the diagrams exhibited by the author the abscissæ represented the load applied to the wire in kilogrammes, while the ordinates represented the corresponding percentage alterations of permeability under the magnetising forces indicated for each curve.

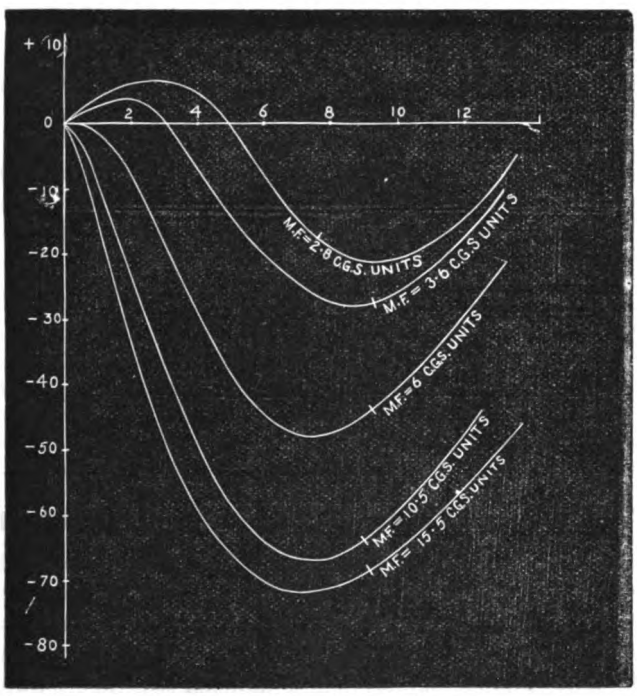


Fig. 1.—Iron Wire, 1mm. in diameter

The first experiment was made with iron wire. The highest load of 12 kilos was (Fig. 1) first applied to the wire, and a magnetising force of one of the values indicated was then alternately applied (always in the same direction) and removed, until the ballistic galvanometer deflection became equal in each case. This operation was then repeated with the load off. Successive loads, beginning at 2 kilos up to 12 kilos, were then applied, these operations being repeated at each step. Two series of experiments were made, the first beginning with the highest value of the magnetising force, and the second beginning with the lowest value, but there was no perceptible difference in the results obtained. As was to be expected, each change of load gave rise to an alteration in the residual magnetism, but the method of observation adopted gave only the temporary effect, this being what was required. Sir William Thomson had already observed that the Villari critical value of the magnetising force diminished as the load increased ; but in his experiments the whole magnetic effect was observed, and the decrease was much less than in the author's experiments, where the temporary effect only was observed. This suggested that a critical point might be found for nickel with respect to the temporary effect only, and curves obtained for nickel in the same way (Fig. 2) as those for iron show the critical point quite as markedly as in iron ; but in the case of nickel the curves show that the critical value increases with increasing load, and for a given load is higher in nickel than in iron. When the experiments on iron wire recorded by the curves shown in Fig. 1 were repeated with the same loads, but at a temperature of 200° C. instead of the ordinary temperature, the curves cut the load-lines twice, so that for a given magnetising force there are two loads which leave the temporary magnetisation unaffected. The same result was obtained at the ordinary temperature by employing greater loads. In this case the wire was lengthened by about 10 per cent. of its original length by loading it nearly to the breaking point, while in the former experiments there was no permanent extension. The maximum decrease of permeability was found to increase with the magnetising force up to a value of the latter of about 16 C.-G.-S. units, after which it slowly diminishes. Permanent extension lowers the Villari point in iron. *The nickel wire in the experiments* (Fig. 2) *was permanently elongated, but it is clear that the curves would not cut the load-line a second time.* Some further experiments with nickel showed that there was very little lagging of the mechanical strain behind the stress, the readings on loading and unloading being very nearly identical. The author in connection with this pointed out that Prof. Ewing had found that nickel exhibits very little magnetic hysteresis.

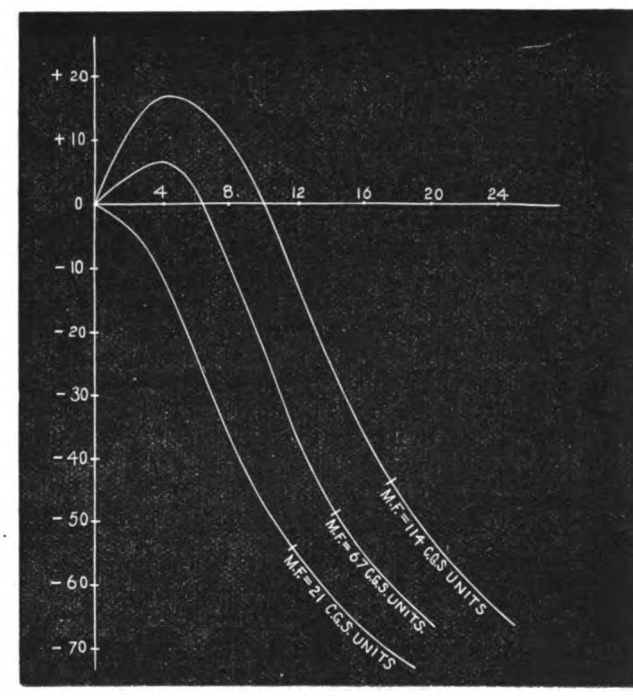

Fig. 2.—Nickel Wire, 8mm. in diameter.

Further experiments on both iron and nickel gave almost exactly the same curves for magnetising forces, varying from 0·03 to 0·3 C.-G.-S. units, and with wires which had been stretched nearly to breaking point there was practically no permanent magnetisation.

The rates for the United Kingdom remain as follows:— 5 0 ... 10 0 ... 19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo, 5s., postage extra.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The Directory was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which is still further enlarged and improved (making 850 pages), is NOW READY. Orders should be forwarded at once to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.

THE INTERNATIONAL TELEGRAPH CONFERENCE.

After a separation of five years the Delegates of the world's telegraph administrations will meet again next month at Paris for the purpose of discussing those varied questions which have, doubtless, arisen in the interval connected with the tariffs and regulations of international telegraph business. There was always plenty for it to do when the Conference met every third year; but now that it meets only once in five or even six years, there is not only more work cut out for it, but much more risk of its adopting premature or ill-considered suggestions, rather than letting them remain suspended for another long term. The attempt on the part of the German Government at the last Conference, which was held at Berlin in 1885, to establish a uniform rate of 20 centimes per word for all European International telegrams, was a case of that kind, though, fortunately, defeated for the time being. It is hoped and believed, however, that the delegates from Great Britain will be equally mindful of British interests on this occasion.

Digitized by Google

On one point, at all events, it may be conjectured that all will have a common interest, namely, in putting the present system of coding on a rational and an equitable footing. It is expected that the regulations relating to code telegrams will come under review at the May Conference; and it is needless to add that there is here a great opportunity for relieving the telegraph systems of one of the worst abuses against which they have had to contend. We may have occasion later on to discuss the proposals which are expected to be placed before the Conference when they have taken a more official and concrete shape; but for the present all that need be said is that uniformity of practice, and intelligible rules for the guidance of the administrations and their customers, would go a great way to remove existing evils which have arisen partly at least through the indulgent laxity engendered by severe competition. If some common understanding can be brought about at the forthcoming Conference, it is pretty certain to be in the opposite direction, and therefore in the right one.

The Standing Committee, as it may be called, which is in permanent sitting at Berne, will do much to facilitate discussion on this and on other important questions which are to be decided by the International Delegates. The International Office, which is placed under the control of the Swiss Government, was one of the first good results of these periodic Conferences. It consists of a Director, a Secretary, and a staff of Clerks, whose duty it is to issue notices of all alterations of tariff, to prepare lists up to date of all established telegraph stations in the world, to keep them all informed of interruptions interfering with telegraphic communication, and generally to compile useful statistics relating to telegraph lines and the traffic passing over them. The office publishes a monthly *Journal* dealing entirely with telegraph affairs, prepares maps and papers for the use of the Conferences, and is in fact the repository of all subjects which are ripe or are ripening for formal discussion among the nations. It is maintained conjointly by all the Governments concerned; and needless to add that without it their quinquennial meetings would be indefinitely prolonged.

The work accomplished virtually through the instrumentality of this useful little bureau since its creation in 1865 strikes us nowadays as almost incredible. Before that date there were almost as many different charges for telegrams as there were places to telegraph to; the methods of counting varied in almost every country, the rates were based on no international coinage, and were extremely anomalous as regards distance and service charges. All this has been gradually altered. Beginning with a basis of twenty words, including addresses, the Conferences have been able from time to time to reduce the charges not only in amount, but in the direction of uniformity. The franc has been adopted as the basis of international rates, and all accounts rendered in the same currency. Extra-European telegraphy came also within its sphere of operation; and in one instance at least, namely, at the Berne Conference of 1871, a substantial increase in the overland charges to India was conceded to the just demands of the private companies. Not until 1875, however, was the distinction between European and extra-European traffic distinctly defined, when the Conference sitting at St. Petersburg promulgated two sets of regulations, the principal difference being that for extra-European telegrams the word-rate was made applicable. Four years later the European systems followed the same course, the London Conference of 1879 establishing the word-tariff for European as well as extra-European telegrams, with the judicious limitation in respect to the former of five words as the initial charge. After this heroic act the delegates rested from their labours for six years; and at the Berlin Conference of 1885 nothing of serious moment was enacted. It would give us much satisfaction to feel assured that the Convention of 1890 will be inspired with the same spirit of prudence and fair play; and although there remains much which the foreign delegates may legitimately do for the welfare of international telegraphy, their proceedings should be vigilantly watched by the official and non-official representatives of British interests on the spot.

REVIEWS.

Electric Light Installations and the Management of Accumulators. A Practical Handbook. By Sir DAVID SALOMONS, Bart., M.A., A.I.C.E. (New edition, revised and enlarged.) (London: Whittaker and Co.)

There can be no better test as to whether or not a book has met a general want than the number of editions which it runs through in a given time; and, judged by this standard, there are few works on matters electrical that have more thoroughly justified their existence than Sir David Salomons' practical little guide to the management of accumulators and electric-light installation. Since its first publication in 1886, no less than five editions of this work have appeared; it has been translated by the French and the Germans, and each new edition has been more bulky than the last, until a work which was originally nothing but a short pamphlet of 20 pages, dealing solely with the management of accumulators, has developed into a respectable-sized tome of over 300 pages, covering the whole subject of private installation work. Although to the electrical engineer the recent additions that have been made to this handbook have not enhanced its value in any considerable degree, yet, to that large class of readers who are desirous of obtaining a few practical hints on the installation and proper running of a private electric light plant, the enlargement of the second part of Sir David Salomons' book must prove very welcome.

That this volume should have met with such a gratifying reception as to necessitate a new edition on an average every year is not surprising when we remember how very much it stands alone. Of books giving the results of and conclusions drawn from laboratory tests we have enough and to spare; but up to the present the author of this little volume is nearly the only person who, having had a lengthy experience of the idiosyncracies of the modern storage cell when operated under ordinary everyday conditions, has made public the phenomena observed and the remedies adopted. Another reason for the success of this work is, we think, to be sought in the author's manner of presenting his facts. He has succeeded in avoiding the tedious minuteness of description so frequently met with in books of a semi-popular description, while at the same time he has not fallen into the error of the expert, who too often takes it for granted that his readers know as much about his particular subject as he does himself.

As the present edition is nearly double the size of its predecessor, it may be useful to note some of the more important additions. The first part, relating to storage cells, although of course it has not been enlarged to such an extent as that dealing with general installation work, contains, nevertheless, considerable new matter. Part II. has been augmented by two new chapters, those on "Alternating Currents" and "Testing," while all the old chapters have been largely added to, and the number of illustrations increased. The chapter on alternating currents deals with this subject in a very general way, and is mainly devoted to an explanation of Mr. Gisbert Kapp's ingenious regulating transformer, and to a somewhat disquieting list of the precautions to be taken in the case of a house connected to the mains of a transformer system. In Chapter VII. the necessity of making proper insulation tests is strongly insisted on; though the author's good advice is neutralised by his recommending the employment for this purpose of an "apparatus consisting of a high-resistance galvanometer of the Post Office

Digitized by Google

pattern, and a few portable Leclanché cells." With such a compact and practical piece of apparatus as the Goolden-Evershed ohmmeter (see *Electrician*, December 13, 1889) in the market, the use of the Leclanché cell for such tests should be a thing of the past.

In so widely read a work as the one we are considering, it is especially to be desired that there should be as few ambiguities or inaccuracies as possible; and we therefore trust that the few we have to notice will be eliminated in the sixth edition, which is no doubt already in hand. On page 278 we are told that "the effect of the successive reversals of magnetism in iron causes it to heat, and this phenomenon is termed hysteresis." The heating of the iron is certainly in part due to hysteresis; but it is *not* hysteresis, which cannot be better defined than, in the apt phraseology of Prof. Ewing, as "a tendency to persistence of previous magnetic state." The following statement on p. 281 also seems to us somewhat misleading: "If the apparatus were perfect, when the house is using no current the primary coil should likewise pass no current. This result is produced in consequence of the self-induction the apparatus possesses, and which acts like counter E.M.F., and the phenomenon is called 'impedance.'" The damming back of the current would more correctly be described as due to the "inductance" of the primary wire; since "impedance" is a *quantity* equal to $\sqrt{R^2+p^2L^2}$, and not in the usual acceptation of the word a phenomenon at all. We would also remark that the Board of Trade unit is 1,000 watt-hours, and not 1,000 watts as stated on p. 246.

These inaccuracies are pointed out in no spirit of captiousness, but, in a book so largely read by the amateur and the learner, ambiguities of expression are likely to give rise to confusion of ideas.

"The Electrician" Electrical Trades' Directory and Handbook for 1890. (*The Electrician* Printing and Publishing Company.)

The Electrical Trades' Directory and Handbook for 1890 is a volume whose merits cannot be fairly judged by mere inspection or even by careful examination of its contents. It is not until one has used it for several weeks that it is possible to compare it with previous issues. The Directory proper, occupying, as it does, about one-third of the volume, is clearly divided by coloured edges into four parts, and has not only been largely increased, to meet the growth of the industry, but the classifications have been carefully revised, and contain several references to the other portions of the book, *e.g.*, list of central stations.

The first third of the volume may fairly be described as an electrical Whitaker, and it merits this description, both on account of the value of its contents and of the accuracy of the compilation. A good deal of the information it contains, such as the tables of foreign import duties, and those showing the progress of lighting stations, tramways, lists of orders granted, and of notices of applications, would with difficulty be obtained elsewhere, while the tables of wire gauges, resistances, current densities, &c., are, as far as our habitual use of them has gone, in many respects preferable to those in the pocket-books, which are too large to be kept in the pocket, and too small to find among the papers which accumulate on most office tables. The Biographical Section has been enlarged, and eight new portraits have been added, besides the excellent steel engraving of Dr. Hopkinson. A. P. T.

Aide-Mémoire de l'Ingénieur-Electricien. By G. Duché, B. Marinovitch, E. Meylau, and G. Szarvady. Second Edition. Revised and enlarged by M. P. Juppont. (Paris: Bernard Tignol.)

It is, we believe, generally understood that the electrical engineer of the near future is to be a close approximation to omniscience; and the publication of pocket-books such as the above certainly points to this. In the "Aide-Mémoire de l'Ingénieur Électricien" is contained the whole theory and practice of electricity, with the addition of from 30 to 40 pages on Heat, Acoustics, and Optics. So exhaustive, indeed, is the information given, that it includes foreign money tables, data relating to the speed of horses, pigeons, and infantry soldiers, formula for the solution of triangles, &c., &c. The result of this attempt to cover so much ground is that many subjects of real use to the electrical engineer are either omitted altogether or unduly compressed. Transformers occupy some five pages, electric meters three pages, and the fifteen pages devoted to the subject of tests are mainly taken up with those of a laboratory character. Compression, not extension, should be aimed at in the next edition of this pocket-book.

Laxton's Price Book for 1890. (London: Kelly and Co.)

The contents of this well-known annual publication are quite up to the mark of previous years both as regards quality and quantity. In the small space allotted to electric lighting—seven pages last year and eight this—a considerable amount of useful information is to be found. We notice, however, one rather important mis-statement. In February, 1889, judgment was given by the Court of Appeal in favour of the Edison-Swan Company, so that it is somewhat erroneous to state in February, 1890, that "The cost of the incandescent lamps promises to be much reduced in consequence of the decision against the Edison-Swan Company as to its patents."

Annuaire pour l'an 1890, publié par le Bureau des Longitudes. (Paris: Gautnier-Villars et Fils).

The 1890 edition of the "Annuaire" is as replete as ever with valuable scientific information of all sorts. Some sixteen pages are devoted to tables of the magnetic elements for 1890, for various places in France and elsewhere, and in the eight pages allotted to electricity some useful data are given with respect to the E.M.F. of various voltaic and thermo-electric couples, and the resistance of metals and alloys. The "Annuaire," we may add, is now within measurable distance of its 100th anniversary, having been first published in 1796.

Electric Testing of Telegraph Cables. By Colonel V. Hoskiaer. (London: E. and F. N. Spon.) Third edition.

The third edition of Colonel Hoskiaer's valuable and much used guide to the art of practical cable testing has been both revised and enlarged. The typography, as well as the plates, are excellent, and the various tests are briefly and clearly described. We commend this little work to all who wish to obtain a good insight into the practice of cable testing.

Instructions for Fixing and Working Dynamo Electric Machines. By W. C. Mountain.

This is a little pamphlet of some 16 pages containing practical hints of the kind likely to prove of use to those who are left in charge of electric machinery without having had much previous experience of dynamos or motors.

RECALESCENCE AND DECALESCENCE.

Something less than a year ago, writes Mr. Robert Shand, in the *Electrical World* of March 8, a somewhat brief experimental investigation of the subject of recalescence was made by Prof. Elihu Thomson. New phenomena were then observed which meet to a considerable extent the suggestions made by Sir William Thomson on the occasion of the reading of Dr. J. Hopkinson's inaugural address at the Institution of Electrical Engineers. I will state my recollections on the subject.

While engaged in the early development of his now well-known method of welding by electricity, the attention of Prof. Thomson was strongly arrested by the magnitude of the recalescence phenomenon; it was then frequently pointed out by him, and the investigation above referred to was subsequently undertaken with the view of determining some of the changes undergone by the material at temperatures around the critical one at which the effect showed itself. The results of the investigation can be stated quite briefly, as follows:—

1. The temperature of *decalescnce* and the quantity of heat rendered latent during the heating of the material was found, within the range of observation, to bear a certain definite relation to its hardness, presumably to the percentage of combined carbon contained in it. The hardest specimen of steel submitted to observation possessed the highest critical temperature, and recalesced with most vigour. Softer specimens of steel

Digitized by Google

tested under the same conditions showed recalescence waves less in magnitude and occurring at lower temperatures. With soft iron bars the effect was not observed.

2. The temperature of *decalescence*, *i.e.*, the critical temperature at which the material *cooled* while heat was being supplied to it, was higher than the temperature of recalescence during cooling.

3. Heating the material from a point a little below, to one a little above, the critical temperature, and vibrating the temperature thus many times in succession, seemed to induce in the material a condition of exhaustion; at any rate, the magnitude of the phenomenon was lessened by such treatment. Allowing the material to cool off, or raising the temperature considerably above the critical point, restored to the material the power of vigorous recalescence.

It would be exceedingly interesting in this relation to ascertain by measurements, closer than were possible with the apparatus constructed by Prof. Thomson, whether or not it is possible that the same piece of steel, at the same temperature before and after recalescence, can exist in two different states as regards its capacity for magnetisation.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

ALTERNATING v. CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY.*

By H. Newman Lawrence, Member, and Arthur Harries, M.D.

Much attention has lately been drawn, both in England and America, but especially in the latter country, to the dangers to which workmen and others are exposed when handling and working with wires, dynamos, and other apparatus connected with the generation and supply of electric currents for light and power. A lively controversy regarding the relative safety of continuous or alternating currents has resulted; but little, if anything, has been done to throw direct light upon the matter, and great difficulty is, therefore, experienced by disinterested persons in arriving at a satisfactory conclusion. It is with great diffidence that we venture to offer this short Paper on the subject, as the experiments and observations upon which our contribution is based were not specially undertaken with the object of throwing light upon it. They form part of a series of data connected with investigations upon which we are engaged with the hope of solving some of the physiological problems occurring in the course of our electro-therapeutic work at the Institute of Medical Electricity. The results obtained from some of our experiments (hereinafter given in detail) led us to note how strongly they bore on the question now before us. We, therefore, after verifying them by repetion, thought it well to invite discussion upon them, and now offer them for your consideration, with full consciousness of their imperfection. They differ from the experiments of D'Arsonval, Harold P. Browne, and others, in the important point that they deal, not with the bodies of rabbits, dogs, and horses, or other animals (from which conclusions regarding human life have to be evolved), but directly with the human body. We do not in any way propose to touch upon the question of the manner in which accidents with electric wires, &c., occur, or how they they may be prevented. It would be manifestly beyond our province to do so. Our object is rather to compare the physiological action of the two forms of current *after the contact*, accidental or otherwise, has been made, and to arrive at some conclusion as to the danger ratio which one form of current may bear to the other under such conditions.

As may already have been gleaned, our experiments have not been made with the powerful currents dealt with in electric lighting and distribution of power. We used small currents, for the most part at low E.M.F., and have directed our attention to—

1st. The determination of the resistance of the human body and skin to the passage of currents under certain conditions; and,

2nd. A comparison of the sensations produced in the human body by passage of the two forms of current.

1st. With regard to the resistance of the human body and skin. In his Lumleian Lectures, delivered before the Royal College of Physicians in April, 1886, Dr. W. H. Stone gave some very useful information. His experiments appear to have been carried out with care, and the results, therefore, are reliable. In the course of many similar experiments we find no reason to differ in the main from the figures he has arrived at, and we quote those that refer to our immediate subject in the following table:—

* Paper read March 27, 1890.

Table A.

—	Resistance, Foot to Foot.	Resistance, Foot to Hand.
Mr. T.	945 ohms	1,320 ohms
Mr. S.	930 „	1,027 „
Hungarian Giant	930 „	1,032 „

There is, however, this important fact to be taken into account, when considering the bearing which these figures have on the present question, viz.—that Dr. Stone, having a direct therapeutic object in view, was dealing (as far as he could) with the internal resistance of the body, and not with its total resistance as represented by that of internal tissues and skin in its normal insulating condition. Further, Dr. Stone's experiments were scarcely typical of results to be expected from either purely continuous or purely alternating currents; for in his lecture he says, with reference to the experiments quoted in Table A, that he had in "circuit a Wheatstone bridge of a rather particular form, a commutating key so as to send the current in opposite directions, &c."

Some experiments conducted by Mr. William Lant Carpenter, however, are more in accordance with the conditions which this Paper is intended to illustrate, as they enable us to form some clear idea of the nature of the current actually used.

The results of these experiments, published in August, September, and October, 1883, in *Health*, are shown in

Table B.—*Continuous Currents.*

—	Resistance from Foot to Foot, in Ohms.	—	Resistance from Foot to Foot, in Ohms.
Dry skin	— min. 10,300	Salt and water...	30 min. 1,400
Salt and water	1 „ 4,300	„ ...	35 „ 1,290
„ ...	5 „ 2,500	„ ...	40 „ 1,250
„ ...	7 „ 2,100	„ ...	45 „ 1,230
„ ...	10 „ 1,900	„ ...	50 „ 1,200
„ ...	15 „ 1,720	„ ...	60 „ 1,190
„ ...	20 „ 1,540		to 1,200
„ ...	25 „ 1,470		

Our own experiments have been made with the skin *normally dry* and *moist*, and we have selected measurements taken from hand to hand, as the hands are the parts most likely to come into contact with wires and other conductors.

The first series of readings are those of resistance to continuous current. They were taken by the ordinary Wheatstone bridge method with a mirror galvanometer. Tin electrodes, each of 50 sq. cm. area, were used, the extended palms being placed upon the electrodes.

The results are shown in

Table C.—*Resistance to Continuous Currents.*

Subject.	Age about	Dry.	Moist with Distilled Water.	Moist with Salt Water.
	Years.	Ohms.	Ohms.	Ohms.
1	35	39,000	19,700	9,170
2	22	49.000	7,700	5,900
3	35	41,400	23,000	11,000
4	38	40,000	11,500	5,900
5	35	50,000	9,500	5,900
6	40	45,000	30,400	26,400
7	21	19,000	7,600	6,700
8	22	27,000	25,400	12,000
9	26	31,000	7,000	6,500
10	24	40,000	10,700	7,000

In estimating the measurement of resistance to the continuous current we must remember that, as the result of the almost instantaneous congestion which follows the closing of the circuit, *resistance is to a certain extent diminished*. Very shortly this is succeeded by polarisation, and by the conditions which accompany the conversion of the body into a secondary battery, and there is consequently a considerable increase in resistance when the passage of current is continued for an appreciable time. On the other hand, the passage of alternating currents is accompanied by a diminishing resistance from the outset, for the early physiological congestion is followed neither by polarisation nor by the electrolytic action which it is usual to expect when the continuous current is used. Table D shows the resistance to alternating currents of the same ten people taken with the same electrodes on the same occasion as those referred to in Table C.

Digitized by Google

TABLE D.—*Alternating Currents.*

Subject.	Dry.	Moist with Distilled Water.	Moist with Salt Water.
	Ohms.	Ohms.	Ohms.
1	2,900	2,500	1,500
2	10,400	1,800	1,200
3	5.500	1,600	1,600
4	2,500	2,200	1,200
5	5,400	1,600	1,500
6	2,600	1,700	1,300
7	1,400	1,450	1,250
8	2,350	1,500	1,400
9	3,500	1,500	1,600
10	5,000	1,375	1,500

Tables C and D are fairly comparable as regards the same individuals, though the maximal differences are strongly marked.

Dr. Stone, in his lecture above referred to, mentioned a very important fact, which since appears to have been overlooked, viz., that (under the conditions he adopted) the resistance of the human body was only about half as great for alternating currents as for the continuous current. This statement we have never seen questioned, and our own experiments show that, under conditions more assimilating to those likely to occur in practical work, the proportion is considerably greater. Table D shows wide variations in the resistance of the individuals tested, as well as other peculiarities which are no doubt partly due to errors of observation, but more largely due to physiological conditions which are scarcely relevant to this Paper; but the tremendous difference between the resistance to alternating currents and the resistance to the continuous current is clearly and definitely marked, and justifies us in drawing certain conclusions therefrom. We find the :—

	Ohms.
Average resistance to the continuous current, moist with salt and water	9,557
" " " alternating " " " "	1,405
" " " continuous " " distilled "	15,250
" " " alternating " " " "	1,722
" " " continuous " dry	38,140
" " " alternating " "	4,155

This difference is illustrated in the comparative-resistance diagram (Fig. 1).

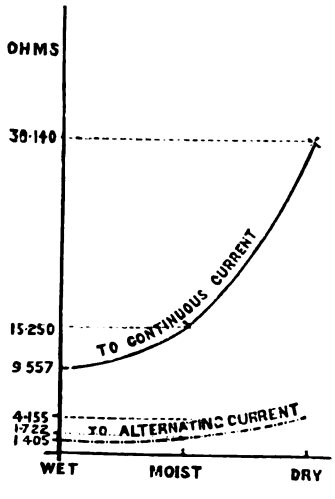

FIG. 1.

When this condition of things became apparent we thought it well to confirm our experiments by repeating them as far as possible under conditions such as would occur in actual working. The results of this set of control experiments we give in Table E. The ten persons tested were chosen so as to be, as far as possible, representatives of those likely to come in contact with electric light and power wires and other conductors. Five were workmen with hands hardened and rendered by toil, as far as may be, insensitive to electric currents. The other five were men accustomed to brain work, and may be taken as representing the occupiers of houses likely to use the electric light, and occasionally to come into contact with the leads, terminals, lamps, &c., of house installations. The electrodes used were of plain metal, and could be grasped in the hand, and so may be taken to represent the metal about a dynamo, or a bare wire or other conductor, which might be grasped accidentally by a workman occupied about a lighting or power station, or by a gentleman investigating some electrical irregularity in his own house. The continuous-current tests were made with a Wheatstone bridge of Post Office pattern, and a mirror galvanometer. The alternating-current tests were made with one of Kohlrausch's rheometers, in which the balance is observed through a telephone. The alternating currents obtained from the induction coil of the instrument had a periodic frequency of about 300 per second. The dry readings were taken with normally dry hands. The moist readings were taken after the hands had been dipped into ordinary tap water.

TABLE E.

Subject.	Resistance in Ohms.			
	Dry Hands.		Moistened Hands.	
	C.C.	A.C.	C.C.	A.C.
1	36,000	2,200	25,000	1,450
2	17,000	1,850	9,000	1,400
3	7,000	1,800	6,400	1,600
4	12,000	1,400	5,900	1,275
5	18,900	1,600	14,700	1,450
6	8,400	1,450	3,900	1,200
7	10,450	1,000	7,500	1,300
8	8,500	1,500	7,300	1,450
9	14,300	2,000	10,900	1,600
10	12,200	1,900	6,900	1,650
Average.....	14,475	1,740	9,750	1,437

These results indicate that the resistance of the human body to continuous current is 6·8 *times* greater than it is to alternating currents when the skin is moistened, and 8·3 times greater when the skin is in its normal condition and not moistened by artificial means. Starting with the statement of Dr. Stone that when the skin has been well soaked with a conducting fluid, and electrodes of large area are used, so that little, if any, more than the internal resistance of the body comes under observation, the resistance to the continuous current is nearly double that to alternating currents (*The Electrician*, April 23, 1886, p. 480), we find that the ratio increases conversely with the moisture of the skin, till in the normal condition we reach the maximum of 9·1 for contact of small area, and 8·3 for contact obtained under ordinary working conditions.

We now come to the second part of our subject, viz. : A comparison of the sensations produced in the body by the passage of the two forms of current. The sensitiveness of persons to the continuous current varies very much, quite independently of variation of resistance. But we find that most people (and we have tested some hundreds) can bear without discomfort the passage of 10 milliamperes for a short time ; and therefore, for the purposes of this Paper, we will consider that amount of current strength as the maximum which may be passed through the body without producing unpleasant sensations. With alternating currents, however, a very different state of things is disclosed ; for having in the course of our therapeutic work found the great need for accurately measuring the alternating currents from induction coils, we obtained from Germany (after failing to find a suitable instrument of English make) a galvanometer recording milliamperes of alternating currents, and, on putting it in circuit with a patient, were surprised to note that before the needle indicated the passage of a single milliampere the patient complained that the current was too strong, and practically unbearable. This, of course, led to further investigation, with the result that, though we tested a large number of persons of varied ages and of both sexes, we found only a few who could bear with comfort the passage of one milliampere of alternating currents.

Table F shows the result of sensation tests made upon the ten subjects above referred to.

TABLE F.—*Sensation Tests.*

Subject.	Without Discomfort.		Muscular Fixation.
	C.C.	A.C.	A.C.
	Ma.	Ma.	Ma.

[Experimental sensation tests were here shown.]

Digitized by Google

So far, we seem to be justified in putting the limit for alternating currents at two milliamperes, and we wish it to be understood that any advance upon this limit means extreme discomfort. Beyond that point violent muscular contraction, rendering relaxation of grasp first difficult, and then impossible, produces distinct pain, which agitates the whole body. We can therefore confidently state that, as far as sensations are concerned, the human body can bear with ease at least five times as much of continuous-current strength as of alternating-current strength. When this fact is taken in connection with the great difference in the resistance offered by the body to the two forms of current, it leads to the conclusion that the danger of unpleasant consequences, and possibly (if not probably) of loss of life when currents of equal voltage are handled, is 34 times ($6{\cdot}8 \times 5$) greater with moist hands, and 41·5 times ($8{\cdot}3 \times 5$) greater with dry hands, when alternating currents are used than when the continuous current is employed. These figures we will adopt as representing the *danger-ratio*.

As a practical example of this conclusion we may take the Board of Trade limit of pressure at which currents may enter houses, viz., 200 volts, and assume that a man having the average resistance taken from Table E handles naked wires within the house.

$$\text{With the continuous current (dry hands)} \Big\} C = \frac{200}{14{,}475} = 13{\cdot}5 \text{ milliamperes.}$$

He thus receives only 13·5 milliamperes, which is little more than, as shown above, he can take with perfect impunity.

$$\text{With alternating currents (dry hands)} \Big\} C = \frac{200}{1{,}740} = 115 \text{ milliamperes.}$$

He thus receives 57 *times more current* than he can bear without discomfort, and the danger of physiological shock is correspondingly increased.

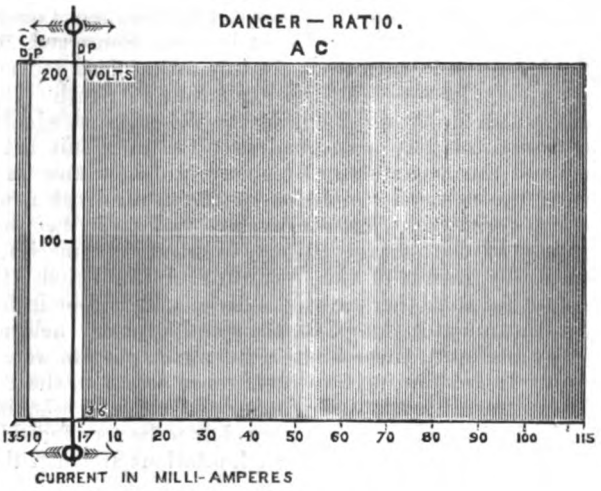

FIG. 2.

The total area on the left side of line O illustrates the amount of *continuous* current (C C) at 200 volts pressure, which will pass through a man making contact with *normally dry hands*. The area on the right of line O shows the amount of *alternating* currents which will pass under same conditions. The plain area on each side shows how much of such currents lie on the *safe side* of discomfort point (D. P.), while the shaded portion shows what lies on the *unsafe* side of D. P. A comparison of the two shaded areas expresses the danger ratio.

Fig. 2 diagrammatically illustrates this danger-ratio. It may be objected that all this has little relevancy when large currents of either kind at high potentials, have to be dealt with; but we would submit that what we have proved to be the case with small currents and low potentials may be fairly taken to be intensified as the current strength and E.M.F. increase. There is at present no reason to suppose that the ratio of resistance diminishes, or that of the sensations becomes lessened, though it may possibly happen that with increased current strength or higher potential the absolute resistance may vary.

What the minimum current of either kind which will destroy human life may be, we are not in a position to say; though D'Arsonval, in his report on electro-physiology made before the International Congress of Electricians held at Paris, 1889 (*The Electrician*, August 30, 1889), says, referring to his experiments on rabbits, guinea pigs, and dogs:—"With a machine of 8,000 volts a momentary closing of the current caused the animal (a rabbit) to make a prodigious leap, but did not cause death immediately; a second application was necessary." "An alternating Gramme machine only causes death above 120 volts mean potential." These statements are not very clear, but we gather therefrom that while a continuous current machine having an E.M.F. of 8,000 volts did *not* instantly kill a rabbit, yet an alternating-current machine having a mean potential of 120 volts did. We feel sure that no hard-and-fast lines can be laid down on the subject. *Individual resistance and individual sensitiveness vary so much and so unexpectedly* that a current which might be taken with impunity by one person might be more than enough to kill another.

With regard to danger ratio, D'Arsonval seems to more than bear out the conclusions that we have arrived at, though he gives no information as to the current strength used. Independently of the kind of current used, the character of the contact made, the surface area of the body involved, and the suddenness of closing or opening the circuit must each and all play an important part in the result. Shock varies with the form of current employed: thus with continuous current only a "make" initial shock is possible, while with alternating currents the initial shock may be either a "make" or a "break" shock. As "break" shock is admitted to be the more marked of the two, independently of the steady diminution of resistance to alternating current, it is probable that the effects of an initial shock with alternating currents of similar strength may be more disastrous than that with continuous current.

DISCUSSION. (AUTHORISED ABSTRACT.)

Prof. FORBES said that although the comparisons of the effects of alternating and continuous current were very interesting, the tests made and the results obtained had little bearing on the practical question of safety in the use of electricity for lighting and power purposes; for the conclusions arrived at in the Paper were not in accord with actual experience. He was willing to admit that he could not bear so many volts alternating as those continuous; but the difference was comparatively small, certainly nothing like so great as the authors would have him believe. The sensations, he said, depended not on the mean current, but on the maximum value of the current or volts, and in the case of an induction coil the volts on break were immensely greater (20 to 50 times) than the minimum occurring in a well-designed alternator, which would send the same mean current through the body as that indicated by the measuring instrument used.

Mr. KAPP concurred in Prof. Forbes's views as to the great difference existing between the conditions under which the experiments were made and those occurring in practice as regarded alternating currents. From experiments he had tried himself, he found he could bear 100 volts continuous with about the same discomfort as 40 volts alternating.

Major CARDEW agreed with Prof. Forbes's statement about the much greater maxima obtained with induction coils than with alternating machines, and said that great differences existed in the shocks received from different machines, even when the measured volts were the same. For example, shocks received from old Wilde machines were very severe, even when the volts were small; he had known a man to be nearly killed by a 300-volt machine of that type, whilst from a modern alternator 100 volts might be taken without great discomfort. Speaking of the resistance tests in Table E, he remarked on the great differences in the resistance of individuals to alternating and continuous currents, and on the disproportionality between them; these differences he believed due to polarisation of the electrolytes in the body. As regarded sensations, he had reason to think that the effect of a given current depended on the volts employed to send the current. Referring to the Board of Trade regulations, he informed the authors that permission to use 200 volts alternating on consumers' circuits had never been granted.

Dr. STEVENSON agreed with the last speaker as to the current from a large battery producing more powerful sensations than an equal current from a smaller number of cells.

Mr. SAYERS thought sensation depended greatly on the shape of the E.M.F. curve and on the frequency of alternation.

Mr. WYLES said he once saw a man come into contact with a Brush 35-lighter; fortunately, he fell away from the machine, and the only after effect was a pain across the chest.

Mr. E. T. CARTER asked whether the resistances to continuous currents were all obtained with the same current strength, or whether various strengths were used in each case, for if there was polarisation, resistance would vary with current. He also inquired if the effects of purely transient currents, such as discharges from cables, and of electrostatic capacity, had been investigated; and asked what was the effect of alternating currents of frequencies less than 300 per second.

Mr. CROMPTON said he had recently tested the resistances of individuals by Evershed's ohmmeter, 100 volts being used in all cases. As a rule he found the resistance to fall from 30,000 or 40,000 to 25,000, by continued application, and in some cases 10,000 or 11,000 ohms were indicated. Children usually gave 8,000 to 10,000. One person whose wrist had recently been subjected to a surgical operation gave a resistance of 25,000 from hand to hand, but on placing one electrode on the part operated on, the resistance fell to 14,000. The sensation effects varied greatly in different individuals, for some whose resistances were 30,000 experienced much greater discomfort than children with 10,000 ohms resistance. As to alternating currents, he believed that there was a general concensus of opinion that only about half as many alternating as direct volts could be borne. Some time ago he, in conjunction with Colonel Armstrong, had made experiments to see what current one could bear, and they found that at 15 milliamperes the skin below the electrodes became hot, whilst at 35 milliamperes the skin was scorched in a few seconds.

Mr. F. H. NALDER suggested that the differences between the resistances with wet and dry hands might be due to surface leakage.

Mr. JOYCE said that, even if they admitted the difference in the E.M.F. curves of induction coils and alternators in producing sensations, as

Digitized by Google

pointed out by Prof. Forbes, yet from Table E one could see that there was a great difference between the resistances of the body to alternating and continuous currents. This of itself meant a serious difference in the "danger ratio."

Mr. W. H. PREECE believed there had been more nonsense talked about that subject, particularly on the other side of the Atlantic, than on any other with which he was acquainted; and they were indebted to the author for clearing the ground a little. He himself had had the misfortune to receive the discharge from a Leyden jar and to be transfixed to a 2,000-volt Brush machine. He was also in the habit of receiving shocks from continuous currents of about 25 milliamperes without experiencing as much unpleasantness as he had just felt with a current of two milliamperes from the induction coil. This led him to inquire whether the instrument used to measure the latter current was accurate. Quite recently he had received an account of an accident whereby a man was subjected to a shock from a 1,200-volt circuit; his fingers were burned, and he was rendered insensible for 10 minutes. Speaking of the so-called "dangers of electricity," he said the difficulty was to kill, rather than to prevent being killed, and that the question was not one of high or low potentials or alternating *v.* continuous currents, but of overhead *v.* underground mains, and bad or good workmanship and insulation. In his opinion it should be impossible for any one to accidentally come into contact with house circuits.

Dr. HARRIES said he had anticipated more discussion on the physiological points raised. Referring to Prof. Forbes' views, he remarked that the high voltage on breaks meant little if the resistance was high. In reply to Major Cardew, he said the differences in resistance depended entirely on the normal state of the skin, and that polarisation did not play an important part, for in the continuous-current experiments the contacts were instantaneous. As regarded the effect of frequency, he stated that the greater the frequency the less unpleasant a given current became. Mr. Crompton's results in the main confirmed their own, but had thrown doubt on the polarisation effect. However, Dr. Stone had shown that it existed, and the first fall of resistance was accounted for by the congestion of the part touched.

Replying to the electrical points, Mr. LAWRENCE said the frequency of the alternating currents was about the same in all the experiments, and that from greater frequencies he would expect less effect. As to the accuracy of the milliampere meter, he said he would be glad to have it tested by anyone interested. They themselves had had it tried by an experienced firm, who reported it to be within 5 per cent.

Mr. ALEX. SIEMENS (who was in the chair), in proposing a vote of thanks to the authors, said they had heard a great deal about the dangers of electricity, but nothing about its beneficial applications. He himself had experienced its pain-alleviating properties in the case of teeth extraction. The positive terminal of a battery was held in the hand and the negative attached to the forceps, and the pain was very slight compared to that experienced in the ordinary methods of extraction. The effect, he believed, was due to the nerve being cauterised by the current; and he suggested to medical men the question whether some such methods could not be adopted with advantage in amputations and other surgical operations.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 22, 1890.

Alternating-Current Apparatus.—There is just now no little interest here concerning alternating current apparatus. A great deal has been said, but very little is known, concerning its actual practical efficiency. In a Paper read last Tuesday evening before the Institute of Electrical Engineers, Dr. Louis Duncan, of Johns Hopkins University, Baltimore, gave a most interesting account of some definite tests made on Westinghouse alternating apparatus of various modes and under various conditions. The points which Dr. Duncan brought out were, in the first place, that the efficiency at full load of alternating apparatus is hardly as great as has been oftentimes claimed for it. The efficiency secured in the tests which he made on a 750-light Westinghouse incandescent dynamo was a trifle under 80 per cent. The largest loss in this case seemed to be the loss in the armature core. The mechanical friction of the machine did not seem to be high, but the magnetic friction, so to speak, was so great as to lower the efficiency of the machine very distinctly. The converters used were the ordinary Westinghouse type, and at full load gave an efficiency of nearly 95 per cent. This efficiency, however, rapidly fell off as the load was lightened. Under ordinary conditions of load the efficiency of the system would be less than 70 per cent. It should be remembered, however, that for the class of work for which that system is used, 70 per cent. is perhaps as high an efficiency as could be obtained from any other system. In attempting to forecast the future of the alternating system, Dr. Duncan expressed himself strongly in favour of large converters operating a considerable number of lights, so that the average load might more nearly approximate to the most economical load. Comparing the alternating and direct systems, Dr. Duncan said that, in his opinion, at the present the greatest average economy would be obtained by combining the two systems, operating the lamps in the compact district near the station by the direct system, and operating the outlying lamps distant from the station by the alternating system. The paper provoked a spirited discussion, in which Mr. Nikola Tesla took a prominent part. Mr. Tesla thought that more recent alternating apparatus than that tested by Dr. Duncan would give more favourable results for the average efficiency.

Storage Battery Decision.—An important decision has just been rendered by Judge Coxe, of the United States District Court, in the infringement suit between the Brush Electric Company and the Julien Company. This suit has been pending for some time, and, before the decision was rendered, the Julien Company obtained an option on the right to become licensees of the Brush Company; the option to remain in force 48 hours after the granting of the decree following the decision. The decision, which is a very voluminous one, is emphatic in favour of and sustains the broad claim of the Brush Company to a storage battery wherein the active material is applied to the plates by mechanical means of whatever kind. Pending this decision the Julien Company have been keeping very quiet, but now are reported as proposing to begin active operations at once under the Brush patent. With this decision, the storage-battery fight is left practically between the Brush Company and the Electrical Accumulator Company, and narrows itself down to a duel between Faure and Brush on the invention in question. An interesting flank movement may possibly be based on the expiration of Brush's Italian patent, which is precisely similar to the ones on which the present decision has been rendered; for in a suit between Brush and the Accumulator Company, which is now in progress, if the decision should be in favour of Brush it would practically give the Brush Company and their licensees a monopoly of the storage battery business in America. If, however, by reason of the expiration of the Brush Italian patent, or for any other cause, the decision should be in favour of the Accumulator Company, the storage-battery field would be left quite open, since Faure's American patents were considerably limited during the interference action in the Patent Office between Brush and Faure. In other words, if the Brush patent is upheld, it is so broad as to be very formidable. If the Faure patent is upheld, its limitations are such that it would be no serious obstacle.

An Alternating Arc System.—Considerable attention is just now attracted to the Westinghouse Alternating Arc System, which is now in use on a practical scale in this city. Its details have not yet been made public, although 125 lights of this system are scattered along the Bowery, and have been giving general satisfaction. As is already known from the advertisements of the Westinghouse Company, it is a series-transformer system, each arc lamp being worked on an independent transformer. The lamps are of 2,000 candle-power, each requiring 10 amperes and 50 volts between the terminals of the lamp. This current is derived from a primary current of 30 amperes on the line, so that the transformation is to increase instead of to diminish the voltage. The Westinghouse Company claim greatly increased light for the carbons under this system. By the use of a flat carbon 2¼in. wide, each carbon being about eight inches long, the Company has been enabled to secure 44 hours' continuous burning, while a ½in. round carbon of the same length gave about 13 hours. As there is no crater formed by the arc, the distribution of light promises to be more even than in ordinary arc lamps. Of course, it will take some time to determine the real merits of the system, but it seems decidedly promising, and on the score of safety is certainly to be desired; since, unless the primary current should break through into the transformer, which is a very unlikely occurrence, the arc lamp may be handled with perfect impunity, save for a possibility of burning one's fingers. The lamp is actually in use, burns

Digitized by Google

with a clear, steady, brilliant light, and has proved so satisfactory that two more circuits, each with 125 arc lamps, will soon be supplied.

Motors.—Just now there seems to be greater activity in the motor field than usual. Nearly all the leading companies report large contracts, and are behind their orders. With the coming of spring, construction will begin actively on a number of new railroads, and activity in that field seems to be specially great. The Julien Company are promising to push their storage system rapidly to the front. There is certainly a great field for it, or any other successful storage system, in this city. And they promise, too, to make experiments in the way of using storage-battery cars on the elevated railroads. It is hard to see the need of them in this particular place, where direct supply can be so advantageously used. There seems to be no little public interest excited in the possibility of electric elevated roads, and the chances are that the many suggestions in this direction will lead to some practical results in the near future.

CORRESPONDENCE.

ALTERNATE *v.* CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your next issue you will probably publish the Paper read last Thursday before the Institution of Electrical Engineers, by Messrs. Harries and Lawrence, comparing the physiological effects of continuous and alternating currents.

As an example of their experiments, a continuous current of 10 milliamperes was passed through the human body without discomfort, and then the alternating current from the secondary of an induction coil (which is a discontinuous current) produced great discomfort when the instrument employed measured two or three milliamperes.

It is only fair that the principal fallacy of their conclusions should be shown at the same time that your journal goes forth to the world disseminating the error.

The instrument employed measures the "effective" current (a kind of average over the period of an alternation). The discomfort, however, measures the *maximum* value of the current during an alternation. With a well-made alternating dynamo the maximum current is about one and a-half times the effective current. But with the discontinuous secondary current, obtained by breaking the primary circuit of an induction coil, the maximum current rises to many times (I estimate 20 to 50 times) the effective current. Thus, the current which caused discomfort was probably 20 to 50 times the current which was measured.—Yours, &c.,

GEORGE FORBES.

34, Great George-street, Westminster, S.W.,
March 31, 1890.

SINGLE *v.* DOUBLE MOTORS FOR ELECTRIC CARS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of January 3, 1890, appeared a reprint of an article contributed by me to the *Electrical World* of this city. Permit me to return to one of the relations set forth in that article. It was shown that under the usual conditions of street-car service in this country, it may be said that one electrical horse-power-hour in the station will effect one car-mile of service on the tracks. This statement refers to a sixteen-foot car, carrying two motors, which, with gearing and switches, weighs from 3,000 to 4,000 pounds.

In your editorial comment, you quite justly referred to the fact that this relation of car-mile and horse-power-hour, as well as several others brought out in my Paper, were founded on data insufficient to establish perfectly accurate values. I have lately been permitted to see the results of a series of tests, more extensive than those reported by me, which confirm my statement as being a fairly good guide for average existing conditions. But in one important particular I think present practice will, ere long, be modified. Instead of two motors on a car, it is probable that only one will be used; and should this change be made, I believe that, *cet. par.*, we might write: 1 E.H.P. hour = 1·25 car-mile.

During the time that I was superintendent of the Sprague Electric Railway and Motor Company (which was the time of development of their railway machinery), it was "borne in upon me," and for reasons too numerous here to mention, that the single-motor method was the better. Yet I was surprised to learn a few days ago that there is, according to some recent tests, a very large saving in the power required for moving a given load, as well as the saving in initial expense, in wear and tear, and in attendance. That there should be some saving of power follows from the fact of taking out one set of reducing gear and motor. But the tests referred to indicate that either this saving is greater than one would ordinarily calculate, or that there is an unforeseen electrical as well as mechanical loss, due to working two series motors in multiple with each other and connected to the axles through gearing in a way now commonly understood.

I regret that I cannot at this writing reach the engineer who made the tests and obtain his permission to give the particulars of his work. I write this to indicate, before its exact value can be had, the nature of a probable correction to a formula quite useful for hasty calculation.

It is, of course, not an easy problem to connect one motor with both axles; but it is desirable, and possible.—Yours, &c.,

O. T. CROSBY.

Room 322, Potter Building, New York City,
March 16, 1890.

DYNAMO AND MOTOR DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The so-called "Authorised Abstract" of the discussion on the above subject which you publish on pages 526-530 (*The Electrician*, March 28th), in so far as reference is made to my remarks, is incomplete and misleading. I trust, therefore, you will allow me space to briefly state the true purport of what I said in reference to the action of the convolutions being commutated; and also in reference to the effect of the lamination of the core in decreasing the divergence between generator and motor. I pointed out that when a wasteful current is generated in the short-circuited coils, this current is obviously of the same direction as the Foucault currents in the iron core, and consequently opposes the motion whether the machine is running as a generator or as a motor, and that it could never assist in the case of a motor, as Mr. Swinburne says it does in his Paper (*The Electrician*, February 21st, p. 401). I then pointed out that these currents and the Foucault currents in the core decrease the magnetic flux in the case of a generator, and increase it in the case of a motor, and that these two actions account for the observed divergences in the E.M.F. generated in the armature winding in the two cases. When there is no wasteful current in the short-circuited coil (which is the case in a good machine with brushes in the position of non-sparking), and the core of the armature is well laminated and insulated, the divergence between generator and motor is reduced to a minimum, and is very small.

From the above it appears that not only is the best possible generator the best possible motor, but that the better the machine the less is the divergence from complete reversibility.—Yours, &c.,

W. B. SAYERS.

Gutta-percha-covered Wires in Cement Conduits.—In an article in the *Annales Telégraphiques*, M. Scheffer, in describing the repairs which he has lately been carrying out on the subterranean lines in Maurienne (Savoy), calls attention to the deterioration of the gutta-percha insulation of wires laid in cement conduits. "The gutta-percha is in most instances impaired, and in consequence the thickness of the dielectric is no longer sufficient to prevent disruptive discharges where high-tension currents are employed." The wires in question were laid in 1885.

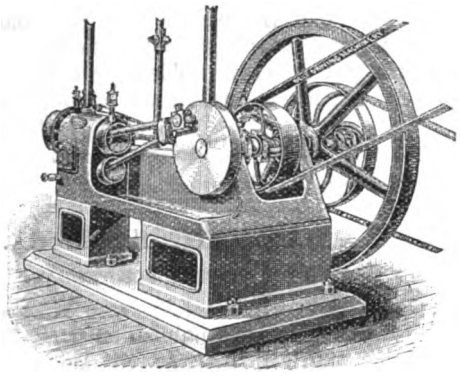
THE "FAWCETT" GAS ENGINE.

The gas engine shown in the annexed illustration is manufactured by Messrs. Fawcett and Co., of Liverpool and London. The chief object in view has been to construct it with as few moving parts as possible, so as to reduce the liability of getting out of order. There are no geared wheels, side shaft, cams, nor clack valves. The whole of the motion work consists only of a slide valve and an exhaust valve, both of which are actuated by one eccentric, as in an ordinary steam engine. The cycle is as follows:—The piston of the compression cylinder on its outward stroke draws a charge of gas and air, and on its return stroke forces the mixed gases into the power cylinder, at the same time driving out half of the waste gases, whilst the returning piston of the power cylinder drives out the remaining waste gases. These operations take place during about half the instroke of the power cylinder piston, when the exhaust is closed, and the compression of the gases is completed during the remaining instroke of the two pistons. The charge is then fired, and the power imparted to the crank shaft in the usual way. It will thus be seen that there is an explosion at each revolution of the engine, and, by an ingenious arrangement of the governor, the force of the explosion and the quantity of gas used is proportioned to the load upon the engine. This engine is thus very suitable for working electric light or other machinery where absolutely steady driving is required.



The following figures are from a test by Mr. T. L. Miller, Assoc.M.Inst.C.E., M.Inst.M.E., consulting engineer, Liverpool, of a 6 horse-power nominal Fawcett gas engine :—

Motor cylinder, 8in. diameter, by 15 $\frac{15}{16}$ stroke.
Compression cylinder, 6$\frac{1}{2}$in. diameter, by 15$\frac{15}{16}$ stroke.
Total gas used, 210·8 cubic feet per hour.
Revolutions, 150·8 per minute.
Indicated horse-power, 11·49 net.
Brake horse-power, 8·52.
Gas per indicated horse-power per hour (main only), 18·4 cubic feet.
Gas per brake horse-power per hour (main only), 24·74 cubic feet.
Mechanical efficiency, ·741.

PARIS ELECTRIC METER COMPETITION, 1890.

The following regulations have been issued for the electric meter competition, inaugurated this year by the Paris Municipal Council :—

1. The competition is open to all inventors of electric meters, for use with continuous currents, alternate currents, or both.

2. The apparatus sent in may be either coulomb-meters or watt-meters.

3. The meter must be direct-reading, and the consumer should be able to ascertain for himself the amount of current consumed.

4. The meters must register small currents : coulomb-meters should act when only ·2 ampere passes ; watt-meters should act for a consumption of 20 watts.

5. The meters, accompanied by a description, must be sent under a sealed cover to the office of the Sub-Director of Works, at the Hôtel de Ville, before the 31st of August next.

6. The meters sent in will be submitted to a committee composed of nine members, five of whom will be appointed by the Municipal Council, and four by the Administration.

7. The apparatus will be submitted to comparative tests as to accuracy throughout the whole of their range, practical efficiency (regularity of working, simplicity, cost, &c.), energy absorbed in working, and disturbance occasioned by their use in a system of distribution.

8. A sum of 13,000fr. will be distributed as follows :—10,000fr. to the inventor who produces a meter giving complete satisfaction and equally applicable to alternate or continuous currents. If the meter is only applicable to one of the two kinds of current, the inventor will only be entitled to half the premium. Premiums not exceeding 2,000fr. will be awarded to those meters designed both for continuous and alternate currents, and 1,000fr. to those meters suitable only for one kind of current which show the greatest advances.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—*Extension of Time.*—Notice is given that the time for sending in tenders for the several sections of the Brighton Corporation Electric Lighting Works has been extended to the 16th day of April, 1890, at 11 o'clock.

TEMPORARY REMOVAL NOTICE.—Messrs. E. L. Berry and Co., electrical engineers and contractors, late of 8, Wardour-street, have taken temporary premises at No. 45, Gerard-street, Wardour-street, during the completion of their new premises.

MESSRS. MARSHALL, SONS, AND CO. (LIMITED).—We have received from this firm a well-printed catalogue of 80 large pages, giving descriptions and illustrations of their well-known makes of engines specially designed for electric lighting, &c. The frontispiece to the catalogue is a large engraving showing the engines and boilers put down by Messrs. Marshall at the Liverpool Exhibition of 1886-87 for the large installation of the electric light there. This installation consisted of three 20-horse, three 30-horse, two 40-horse, one 14-horse, one 10-horse, one 8-horse, and one 4-horse-power Marshall engines and boilers of various types, driving in all 10 dynamos of a total of 85 arc lamps and 1,750 incandescent lamps. Following a comprehensive price list come particulars of the numerous prize medals which have been awarded the firm, amounting to over 250, gold and silver. In the introductory matter Messrs. Marshall announce that they have made upwards of 18,000 engines at their works at Gainsborough, many of which have been specially built for electric lighting purposes. The catalogue is well arranged, and the information contained is all that can be desired. In particular, a very full description is given of a long-stroke horizontal fixed engine, fitted with Hartnell's patent automatic expansion gear. These engines are constructed of from 12 to 35 horse-power, and have been specially designed to reduce to a minimum the expense of steam-power in first outlay and in repairs and maintenance, but especially to reduce to the utmost the consumption of steam per horse-power given out. They have long strokes, large working parts and steam passages, quick piston speeds, and great indicated power; whilst, in uniformity of rotation under the most sudden variation of load, the firm claim that they are a great success. The cylinders are made of cold-blast iron, and are steam-jacketed, with a separate liner forced in. The stroke is twice or more the diameter of the piston. The pipes, ports, and passages are large. The expansion valves are on the back of the main valves. Above 11in. diameter short ports are introduced, and double valves at each end. A stop valve is fixed to the cylinder, and cylinder cocks, displacement lubricators, indicator bosses, &c., are provided. An automatic sight-feed lubricator is also applied. The crank-shaft brasses are in four pieces capable of horizontal and vertical adjustment, a very useful arrangement. The automatic regulator is very powerful and extremely sensitive. There is no throttle valve. The engine is controlled by the regulator, by means of a simple expansion gear, so perfectly that the whole load may be instantly removed with but slight variation in the speed. The cut-off extends to about five-eighths of the stroke. Full descriptions and illustrations are also given in the catalogue of several kinds of engines, boilers, saw benches, saw spindles and carriages, mortar mills, friction hoists, threshing machines, &c., made by the firm. Accompanying the book is a loose sheet giving a list of some of the principal electric light installations driven by engines and boilers made by Messrs. Marshall. The installations number about 200, and include large public buildings (such as the Bank of England, the British Museum, &c.), commercial establishments, shipbuilding yards, mansions, private residences, &c., at home and abroad, representing in all a total of nearly 4,000 horse-power.

MESSRS. W. H. WILLCOX AND CO.—This firm send us illustrated particulars of Entwistle and Kenyon's patent parallel vices, several kinds of which are, no doubt, familiar to our readers. The list includes the bench vice, portable vice, drilling, planing, and shaping machine vices. A number of very favourable testimonials are appended from users in this country and America.

MESSRS. GANZ AND CO.—We have received from Mr. Charles Flesch, Messrs. Ganz and Co.'s representative in Australasia, a pamphlet giving a lengthy description of the Company's system of electric lighting. A long list is given of central stations erected by the Company, comprising the transformer plants, up to the middle of last year ; they are 74 in number, and include several colonial stations.

February 28, 1890.

3,193. J. SWINBURNE. Surrey. Improvements in and connected with transformers, electrical measuring instruments, and insulation.

3,196. S. WALKER and G. MILLS. Lancashire. Electrical and steam application for actuating separate and independent alarms in connection with valves.

3,231. J. SHIPP. London. Automatically regulating and keeping constant the electromotive force or pressure of any electric circuit.

March 1, 1890.

3,272. G. E. FLETCHER. Stockport. Improvements in switches for controlling electric circuits, especially electric light circuits.

3,273. G. E. FLETCHER. Stockport. Improvements in the lighting of railway trains.

3,304. M. C. GREENHILL. London. Improvements in apparatus for enabling a supply of gas or other fluid, or a current of electricity to be obtained for a limited time on prepayment therefor.

March 3, 1890.

3,322. T. KEEP. Birmingham. An improved voltaic battery (T. and S. Morrin, Limited, New Zealand).

3,329. J. CLEGG. London. Improvements in the manufacture of light emitters or illuminants for electric or other lamps.

3,335. A. SCHIRNER. London. An improvement in holders for incandescent electric lamps.

March 4, 1890.

3,419. C. J. VAN DEPOELE. London. Method of and apparatus for producing and utilising pulsating electric currents in closed circuits.

3,472. J. W. LITTLE. London. Improvements in apparatus or appliances for operating electrically devices for informing passengers in railway carriages as to the names of stations on the line, or for conveying to them other information.

3,484. E. SCHWEIZER. London. Improved electrical secondary clockwork.

March 5, 1890.

3,509. C. A. SAHLSTRÖM. London. A portable hot-air, steam and electrical bath, with arrangement for inhaling and otherwise employing vapours, plain or medicated.

3,534. L. W. DE GRAVE. London. A new or improved device for extending the circuit of incandescent lamps.

3,544. F. J. PATTEN. London. Improvements in and relating to electric telegraphy.

March 6, 1890.

3,572. Sir C. S. FORBES, Bart. Improvements in primary batteries.

3,574. H. R. LOW and G. E. B. PRITCHETT. London. Distributing electricity.

March 7, 1890.

3,622. J. CLEGG. London. Improvements in the manufacture of light-emitters and illuminants for electric lamps.

3,654. H. EDMUNDS. London. Improvements in apparatus or means for supplying, distributing, controlling, and metering electric currents.

3,658. J. STEINHEUER. London. Improved electrical signal clock.

3,660. S. B. MCCLELLAN. London. Improvements in apparatus for connecting and disconnecting electric circuits.

3,663. H. EDMUNDS. London. Improvements in means or apparatus for metering electric currents, applicable also for indicating or recording the electrical condition or charge of secondary batteries and the like.

March 8, 1890.

3,697. J. ANDERSON. Glasgow. Improvements in galvanic cells and batteries.

3,717. L. WEIGERT. London. An improved electrolytic solution for galvanic batteries.

3,731. THE MINING AND GENERAL ELECTRIC LAMP COMPANY (LIMITED), and D. G. FITZGERALD. London. Improvements in or connected with the positive elements (negative electrodes in charging) of secondary batteries, which elements are applicable also as cathodes in electrolysis.

3,732. J. HOPKINSON. London. Improvements in electro-locomotives.

March 10, 1890.

3,787. H. W. LIBBY. London. Improvements in electric railways.

March 11, 1890.

3,804. Sir WM. THOMSON. Glasgow. Improvements in rheostats.

3,805. W. BRIERLEY. Halifax. Improvements in electrical terminals. (Heinrich Arld, Germany).

3,840. S. C. C. CURRIE. London. Regulation of alternating generators.

3,841. SIEMENS BROS. AND CO. (LIMITED). London. Automatic apparatus for compensating variation of current in electric conductors (Alfred Mills Taylor, India).

3,842. SIEMENS BROS. AND CO. (LIMITED). London. A circuit breaker for secondary currents from electrical transformers (Alfred Mills Taylor, India).

3,861. B. DEATH. London. An improved holder for incandescent lamps.

March 12, 1890.

3,900. L. PYKE and H. T. BARNETT. London. Improvements in insulation and cooling of electrical inductoria.

3,913. G. KAPP, W. C. JOHNSON, and S. E. PHILLIPS. London. Improvements in alternate current transformers.

3,924. H. H. LAKE. London. Improvements in electric batteries (The Crosby Electric Company, United States).

March 13, 1890.

3,937. W. S. RAWSON and C. S. SNELL. London. Improvements in electric flash signalling lanterns and apparatus in connection therewith.

3,947. J. CLEGG. London. Improvements in the manufacture of light emitters or illuminants for electric or other lamps.

3,960. J. WOOD. London. An improved galvanic medical appliance for use and wear upon the human body.

3,963. W. SCOTT. Glasgow. Improvements in or relating to electrical switches.

3,969. SIEMENS BROS. AND CO. (LIMITED). London. Improvements in switch boards for stations of electrical supply (Alfred Mills Taylor, India).

3,984. A. DUVAL and H. NELSON. London. Improvements in or connected with shades, globes, or glasses for electric or other lights.

COMPANIES' MEETINGS & REPORTS.

London Electric Supply Corporation (Limited).

The third ordinary general meeting of the shareholders of this Corporation was held at the Cannon-street Hotel on the 31st ult., under the presidency of Mr. J. S. Forbes.

The MANAGER and SECRETARY (Mr. Charles Waller) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said that the Earl of Crawford, who until very recently presided over the Corporation, had, for reasons of health chiefly, found it incumbent on himself to vacate the chair. His (the speaker's) colleagues had been flattering enough to him to suggest, as the Corporation was about to enter on a new stage—that was to say, as the works were approaching completion, and the Corporation was likely to develope at no distant time into a working undertaking,—that he might be of some service to them by taking his lordship's post. He thought that that was an occasion for adverting to the great services which the Earl of Crawford had given, not only to the Corporation but to electrical science generally, having been a pioneer of science. His lordship had worked incessantly—and, as far as he (the speaker) knew, with no other reward than unremitting labour, great responsibility, and, at present, no profit—in the development of the electric lighting science, and the shareholders' interest particularly. He was sure they must all regret the reason why his lordship had felt it incumbent on him to take a period of repose. He would address them as briefly as possible, and yet somewhat exhaustively with regard to the figures, because this concern, like all others when it passed out of abstract proposition into the region of fact, turned greatly on the figures. The accounts were submitted upon the model required to be made by the Board of Trade, and he thought they rested upon this possibility: that, in accordance with the conditions upon which this and similar companies had come into existence, there might be a time when some other interest—local authority or otherwise—might acquire the right of taking this enterprise over upon certain terms set forth in the Concession Charter, or Provisional Order, as it was called. It therefore became a matter of public interest that the accounts should be stated and carried on from year to year in a fashion that would afford an opportunity in case of need, of the terms and conditions as regarded expenditure and so forth upon which their enterprises might be taken over. With regard to their share capital, the Corporation were authorised by their articles of association to raise £1,000,000, divided into 200.000 shares, and under these powers 111,000 shares had been issued and paid for, representing £555.000, which had gone into the coffers of the Company. For their future requirements there remained to be issued 89,000 shares, representing £445,000, but there was no immediate probability of this part of the capital being increased. Comparatively recently, too, the shareholders authorised the creation of 50,000 Preference shares of £5 each, or £250,000. This was to get rid of the incubus of a debenture debt. Every one who was associated with these enterprises knew the great advantages of depending rather on subscribed capital than borrowed capital, because, where the future was somewhat speculative, from the nature of the enterprise—somewhat uncertain—it was putting too many eggs in one basket to trust to having such a return, or such capital in their possession at a particular moment as might be required to pay off a debt falling due at a particular date. Their debentures had therefore been cancelled, and they were covered by a security equally efficient for the raising of money and safer to the shareholders. The Preference shares had all been issued by the authority of the proprietors, and up to the date of the report £2 per share had been called up, leaving them an unexhausted £150,000 available for the future of the undertaking. The only point they had to consider was whether, with the cash in hand and with the reserve of cash subscribed—that was to say, the balance of the Preference shares and the reserve of force behind in the character of the 89,000 shares—there was such a reserve as was a good foundation for resting upon, and that the extension of the Company from time to time was provided for. They would be able to judge of that when he came to deal further with the distribution of the capital in the next account, No. 2. That was made up in great detail. There seemed to be no fewer than 15 items analysed for the purpose of that account, and generally in its form it was an account prescribed by the Board of Trade for the purpose of showing, as he had said before, from year to year the various items of cost, and establishing the Company and carrying it on. Upon the founding of the business, up to December 31, 1888, the Company had expended £378,830, but that amount for the purpose of carrying forward had been diminished by a sum of £5,127, which was the value of certain material sold and certain depreciations written down. Therefore they started the year 1889 with an expenditure of £373,703, and during the past year they had been spending the shareholders' money in pretty considerable amount and somewhat rapidly, no less than £131,555 having been disbursed within the year. Of course, assuming it was capital which was to have sooner or later a return on it and was sooner or later to achieve an object and establish a going concern as a remunerative business, the more rapidly it was spent the better. The result of these two items put together showed that they had expended up to the 31st December, 1889, £505,258. They had reserved on capital account £649,750, of which there was unexpended at the close of the year £144,491. That was unexpended capital already paid in, and to what portion of it was liquid they had to add £150,000, unpaid on the Preference capital, to estimate the amount of money in the possession of the Company and assured to them in order to complete and develope the undertaking. Beyond that, assuming that they decided upon going in for further orders and concessions, they had the reserve he had mentioned of ordinary capital. It was obvious that, having that large amount of capital at command, there would be no necessity to talk of ordinary capital, as the reserve would be more or less available for the future as the results of the undertaking were more or less successful. As far as the Directors were able to bottom a business of this sort, which had in it some elements of speculation and uncertainty, they had every reason, upon the advice of their engineer and their managers, and acting upon their own judgment, and from the information before them, to believe that the resources on hand were fully sufficient to carry out the undertaking as far as their existing powers were concerned. Going from that, one was obliged to refer to the next account, No. 3, which, after all, was the crux of the whole business. It was astonishing how easily people forgot the conditions of an undertaking in which they embarked. That was an enterprise which had involved a great many speculative quantities, and something also risky—the finding out how practically to develop and give form to the ingenuity or the genius of the inventor. He was one of the few men, he was afraid, left living who had to form the railway system, and he remembered commencing business as a lad when there was no organisation whatever. Everything had to be made. Someone had conceived a railway, but how it was to be done, and when done how it was to be broken as a commercial undertaking, involving daily duties of the most complex and difficult kind, no man had conceived. He went through it all, and therefore, going back to a parallel, this class of undertaking was exactly what the railway system was when the great genius of Stephenson conceived it possible and set to work to do it, and, having constructed it, it had to be made what the railway system was now. This was not done in a day or without many errors, and it was not done without a great deal of risk and a great deal of loss, which every one would have avoided if he had been as skilled then as people had become since. In relation to a thing so subtle and so beyond human knowledge, as electricity was, they had much to find out; and they must not suppose that in this enterprise, any more than in any other, the thing was going to be brought to perfection without a great many mistakes and a great many things to find out. Now, with reference to the revenue account, it meant how far those scientific ideas had been concreted and turned into a commercial concern. Everyone knew that at the outset of an enterprise such as theirs great relative cost had to be incurred in producing a comparatively small result. As in the case of a man opening a shop, they had to go to great expense, and then they had to wait for customers, and customers might come more or less slowly; but obviously, whether they came slow or fast, certain charges, rent and taxes, the machinery, the power whatever it was to keep the thing going, must be paid for. That was the position of the Company; and anyone who supposed that in the first year or two in an enterprise like theirs, in a transition state, and quite uncompleted or incomplete as regarded its entire development, was going to be a very brilliant undertaking in the way of a return on its capital, must have been, he was afraid, without that amount of experience or reflection which ought to guide men of business in matters of this sort. He was sensible that these accounts contained a great many items of expenditure which were very large in proportion to the result achieved. On the other hand, he was equally sensible of the fact that they did compass and cover a great deal more that equally well might have been achieved during the period if the development of the Company, and of such a new, complex, and very difficult business, had been further advanced. The amount expended on revenue account had been £27,638, less a small balance of profit of £1.249. This expenditure would, however, have enabled them to sell a great deal more current at 7¼d. per Board of Trade unit, and a great deal more current under contracts, and to have obtained a great deal more rentals from meters, converters, &c., than they had done if their business had been longer established. It was obvious that the thing must go very slowly until the machinery for generation and distribution was made perfect. They might say Why had it not been? Well, it was very difficult. He hardly knew any enterprise in which Parliament had had a voice which had been so hampered and obstructed as electric lighting. Some of them knew, probably, that the first legislation on the subject was conducted by one of the most able men in the Kingdom, a man who put his heart into it with the view of doing what he thought was strictly just between the inventor, the promoter, and the public—Mr. Chamberlain. He obtained advice from a great many people; but he got alarmed at the representations which were made to him respecting the hardships inflicted on the public by the gas and water companies and it ended in his insisting on conditions in the Electric Lighting Act which made electric lighting impossible, and delayed its introduction into this country for a great many years. After a time people began to ask why they had no electric lighting in England; and it was seen that the

Digitized by Google

reason for this was simply because no one but an idiot would invest his money in an enterprise hampered by such conditions. He himself, though not at the time immediately connected with any electrical company, gave a great deal of evidence before an important Parliamentary Committee; and he pointed out, in language tolerably obvious, he thought, that it was insane to suppose that anyone was going to put his money to any extent into an enterprise resting upon such conditions. The result of that Committee was that the legislation was altered two years ago, and the worst of the conditions were considerably modified, so much so that it became possible to get on with the electric lighting enterprise. They did not, however, get rid of all the conditions under which these companies, and their own Company in particular, had to work. Financially, they were not bad conditions. They entitled them to receive all the profit they could make out of their business without interference, and they gave them the sufficiently long term, 42 years, to make the investment of the capital and its redemption tolerably secure. But still immense anxiety was shown by Parliament to protect the public interests. Not only had they got what were called Provisional Orders, with a great number of conditions, some of them almost incomprehensible, and all more or less conflicting with each other; but, in order to put this state of things right, the Board of Trade, to which, under modern legislation, the conduct of everything seemed to be gravitating—the railway interest, the shipping interest, the electric light interest—were to previse and legislate and to do what the companies themselves had much greater opportunities of doing—to previse and legislate with this great advantage, of having at their backs a vast amount more skill than the Board of Trade could possibly have, and with nothing else to do. Still the Board of Trade must regulate; and to people who were impatient and wanted to know why they did not get on, he would say that they could not move under the present legislation without having to consult a great number of authorities, because their getting on depended on their interference with the public rights and the public streets; and they had to refer to the Board of Trade, the County Council, the local authorities in every parish, the Postmaster-General, the gas companies, the water companies, the telephone companies, and so on, and they could not move until they had satisfied every one of these conflicting authorities. Let them take the Postmaster-General: that official was in possession of the streets. To a certain extent he was a competitor for the occupation of the streets, and they could do nothing without him. Not only must they not interfere with anything which the head of the Post Office had done already, but they must not interfere with anything he might do in the future. This was not a very easy task to perform, and when they had settled with the Post Office they had to go to the local authority, then to the County Council, who were already so much occupied in regulating everything and everyone that they were not always in harmony with either the Postmaster-General, the Board of Trade, or the local authority. They had to steer their way clear and through all these obligations, and they therefore would have to ask the shareholders to be a little patient and forbearing, as he was sure they would be. Of course those difficulties would be overcome with patience and a knowledge of the business. With the expenditure they had incurred on revenue account they could have produced a great deal more current for sale and realised a great deal more money if they had had their mains and appliances for the conveyance of supply more advanced. He knew he was about to enter upon delicate ground and to get into the region of prophecy; but he was bold enough to have the courage of his opinions, though he knew what an astute or probably hostile critic might say next year if he found that, with the larger development of the business, there was no better proportionate result than £1,249 of profit out of £27,638 received. He for one believed that there would be, and that the amount would go on increasing at a very rapid rate when they got over the preliminary difficulties to which he had called attention. He observed that the sum of £1,249 was all the money which they had really got out of the working of the concern, excepting the interest on the deposit account and sundry discounts amounting to £1,003. These two items together would have been the whole fund out of which any question of dividend could have arisen in dealing with those accounts, but for a kind of godsend—that was, the profit on the sale of overhead wires, &c, £3,173. That item arose out of the re-arrangement of the powers of these companies. There were several conflicting companies, but the most important for their purpose was the Metropolitan Company, which was presided over by Sir John Pender and heavily backed. They had got large concessions; in fact, the two companies, the Metropolitan and London together, had got what might be called the lion's share of London. The Metropolitan Company got concurrent powers in certain places with the London Company, and they had to work alongside them. At other places they were turned out, and the Metropolitan Company got exclusive powers, notably in Marylebone and the Strand; but the London Company were already on sufferance there until their Provisional Orders were passed. They had to turn out of Marylebone and the Strand because Parliament had given these districts to someone else; but there were the wires, &c., and the Metropolitan Company, like sensible people, said they had better take these things over. The London Company therefore made a bargain with them which was a great advantage to the Metropolitan Company, to get into immediate possession, and it was a certain advantage to the London Company not to have to pull their wires down and walk out; and the Metropolitan Company paid them a certain price. There were two items there, one distinctly revenue and the other capital. They had taken the capital and written it off; the balance, the part belonging to revenue, had gone to the credit of profit and loss for the year; and it afforded a balance out of which to meet the obligations of the debtor side of the account, and it enabled the Company to pay a dividend on that portion of the Preference capital which had been subscribed up to December 31st, leaving £920 to be carried forward for the benefit of the next profit and loss account. After referring to the reserve fund account and to certain items in the general balance-sheet, he passed on to the Directors' report, and said that they had thought it very important that at the present stage of the business, when a great idea—involving, he was bound to say, a good deal of the unknown, and, therefore, a good deal of possible risk, as well as of sound and immense advantages—had been sufficiently developed and in practice to enable the genius underlying it to speak, as it were, and show the point which it had got to. Upon the Board rested great responsibility and constant labour. They had thought that the shareholders themselves should have had Mr. Ferranti's report appended to the Directors' report, so that the shareholders might discuss it amongst themselves. Mr. Ferranti had told them his own story, and the Directors were so far responsible for it that they published it, and made it part, as it were, of their own report. It was much the more important part of the report, as it dealt in actual figures and facts. This was why they had given it the prominence of the first paragraph in their report, and he commended to their careful consideration what Mr. Ferranti had stated. In the next paragraph the Directors said that they had carefully considered the means of turning to better advantage the plant at the Grosvenor Gallery station. Their enterprise began there. It might, in fact, be described as the pioneer of electric lighting, certainly in London, and, like Topsy, it grew. It was not intended originally for a centre of supply for a great city, and very soon the demand outgrew the possibilities of the position. It was an essential element at present in the conduct of this business, but as soon as they were in full work at Deptford, the position of the Company, and the exigencies of the position in Bond-street, would require that the Grosvenor Gallery should cease as a centre for generating the current, though it would not cease to be a centre of supply. They had decided to remove the machinery to Deptford. Then they said in their report that the applications for current now in hand were growing from day to day. That was quite true; they could not meet the demands of the public upon them at present, and there was nothing like realising the inevitable. People must make up their minds that, until there was a great deal more known about the electric light than there was at present, they must be subjected from time to time to serious inconvenience. He was old enough to remember when gas came in, and when one of the great difficulties which gas companies had was to induce the people to turn out the gas instead of blowing it out, which they had been accustomed to do previously with their candles. People were slow to learn; but in course of time they would learn, as they had in the case of gas, to deal properly with the electric light. Their boundaries and those of the Metropolitan Company were being delimited, and they were now very good friends with that Company, both of them realising that they had a great deal to do and a very fine field for scientific pursuit. With regard to the Preference capital, the Directors had not made further calls, which they might have done, as they thought it more advantageous in the interests of the Preference shareholders themselves, in view of the recent state of the Money Market, that they should only be asked to pay up the unpaid capital as it was required. Moreover, the dividend on the Preference capital was not cumulative, and they had only to pay interest on the portion that was paid up annually. In order, however, to keep faith with the Preference shareholders, and also to keep within the terms of the prospectus, the Preference shareholders had the option, if they desired to exercise it, of paying up the balance due on their shares whenever they pleased between now and July next. He had already referred to the resignation of the Chairmanship of the Company by the Earl of Crawford, and the appointment of himself by his colleagues to that position. He had required some persuasion to believe that he could be of any service to the Board, but they had thought so, and, *noblesse oblige*, he had assumed the duties. He hoped he would be worthy of the confidence of his colleagues and of the proprietors. He desired to impress upon the proprietors the obligation that they owed to the eminent firm of accountants, Messrs. Kemp Ford, and Co., who acted as auditors to the Corporation. They had given great diligence and care in assisting the Board to put the accounts on a thoroughly sound basis. He had now concluded the remarks which he wished to address to them on that occasion. He would not read Mr. Ferranti's report, but he trusted that the shareholders would do so themselves—read, mark, and inwardly digest it. It contained a great deal of interesting information, and the concluding paragraph contained the philosophy upon which they had embarked their money it said:—"It may be well here to remind the shareholders that in erecting its works at Deptford on a site immediately adjacent to the Thames, and upon a sufficiently comprehensive scale, the Corporation has taken its lesson from the gas companies. These companies commenced with small stations in the centre of populous districts; but experience has since shown that this was an undesirable method of proceeding, and that the true way to secure both economy and efficiency is to generate gas on a large scale on a commodious site at the water's edge, and at some distance from the district to be supplied. The Corporation has followed this eminently practical conclusion, and when the Deptford works are further advanced, the wisdom of following an example proved to be so successful in an enterprise of a kindred nature will be apparent." Of course, what was referred to in that paragraph in connection with gas companies was the Becton Works. Everyone knew that the largest gas corporation in London had done exactly what was stated in the paragraph which he had read. First of all, there were a number of detached works all over London, and they had been gradually concentrated at Becton. As to the arguments about a waterside site, they had gone to Deptford with a clear prevision. Coal would be a chief element of expenditure, and they had proved that they could get it delivered there cheaper than at the Grosvenor Gallery. There was one other remark he wished to make. Mr. Ferranti, and the Board of Directors leaning upon him, had embarked on a method different from other known methods—the high-tension system. If Mr. Ferranti had not done this, the London Company would have been in the same "swim" as the other Companies who had taken to the low tension, and they would have all the benefit of the advantages, or, on the other hand,

Digitized by Google

the disadvantages, of that system. If Mr. Ferranti's system were right, the London Company would be in advance of all the other Companies. The experiment was now being tested by practice, and, like all experiments, was not achieved in a single day. But a great many difficulties had been overcome, and a great many things said to be impossible had turned out to be possible. He had had the opportunity of going to Deptford with two very eminent Americans, one of them the great father of this industry, Mr. Edison. That gentleman said that at all events it was a bold and great experiment, and they had nothing like it in America; and he was good enough to express a hope that it might prove a success, in which case it would be a gigantic triumph. Mr. Edison's lieutenant, a man trained by Mr. Edison himself, who had had a great deal to do with the electric telephone, also the other day visited the Deptford works, and was quite as much charmed as Mr. Edison; but he went a little further, and said that what they were doing at Deptford was the right thing—concentration in one place. He added that the great mistake that had been made in America, and particularly in New York, had been in having too many places, and that in that city they were endeavouring to see how they could reduce the number of generating stations by putting three and two into one. He confessed that he had felt a little comfort in those remarks, because the the contention of some was that at Deptford the Company was putting too many eggs into one basket. He concluded by moving the adoption of the report and accounts.

LORD WANTAGE seconded the motion.

In the discussion which followed, Mr. BENJAMIN KISCH, Mr. SCOTT RUSSELL, and LORD KINGSBURGH (Lord-Justice Clerk), took part. The latter stated that he had been reading in an old Blue Book some evidence given by Sir Humphry Davy on the subject of the gas supply. As the Chairman had said, the idea at that time was to have a number of isolated stations, and Sir Humphry stated that it would be absolutely improper, from a scientific point of view, to have any gasometer that would hold more than 20,000 cubic feet, that each gasometer must be built into a stone tower, and that these stone towers must be at least 40ft. apart. Sir Humphry was asked whether he was aware that at the time, in Paris, a gasometer was being constructed to hold 200,000 cubic feet; and he replied that whatever "our more rash French neighbours" might do, he could only repeat, as a scientific man, that no gasometer ought to be built to hold more than 20,000 cubic feet. He could not help thinking about this when, on coming into town on the Midland line, he saw certain gasometers holding seven or eight times as much as the single gasometer which was being built in Paris at the time that Sir Humphry Davy was giving his evidence, and all so close together that one could hardly pass between them. He thought that this incident bore on the point dealt with by the Chairman as to the construction of the works of the Company at Deptford. Another incident which he desired to mention had reference to what the Chairman had said with regard to high-tension current, as to which some persons appeared to be very much alarmed. In an old number of the *Quarterly Review* he came across an article on railways, and after the reviewer had spent about 14 or 15 pages in highly praising railways and saying that they would be of enormous use, he observed, "But what shall be said of the madness of men who propose to run these trains on these iron roads at a speed of 20 or even 25 miles an hour!" And then he expressed a hope that Parliament would act firmly in the matter, and absolutely restrict them to 14, or, at the utmost, 16 miles an hour! He (Lord Kingsburgh) thought they might say that, while restricted by the Board of Trade and some other interests, they had developed a little since then; and that, so far as regarded their Company, they would be able to show that the wisest plan was to have one large central station, and that they need not be afraid, if they took care to have the proper strength, to communicate the current to all parts of London.

The CHAIRMAN, in responding, said that the statement in the engineer's report concerning the mains purchased and laid was a very frank one. These mains were not designed by Mr. Ferranti, but in concert with Mr. Ferranti, and they were carried out by a great manufacturing firm. They were, according to the lights possessed by this particular firm, calculated to do a certain thing. They were to be tested up to 10,000 volts, and they were tested up to that, and beyond, he believed. Among other things they had to find out was that there was a great difference between tests in the laboratory and after the thing was put in the earth. 10,000 volts was in excess of anything they had to stand, and if they had been able to stand half of 10,000, they would have been considered to perfectly answer the purposes for which they were conceived and laid. Unfortunately, however, they did not. He would not at that moment go further into this matter, as it was possible that they might have to resort to law to recover damages for unworkable construction or want of skill. With reference to the question of permanent mains, plenty of mains had been laid for low tension, but for high tension Mr. Ferranti, among other things, had invented his own main—what was called the permanent main; and that main had been manufactured and tested, as far as a test could be applied on a limited length of it, on the Company's own premises up to 20,000 volts; and what Mr. Ferranti predicted was this—that whatever the reason of the defect might have been in the particular main constructed and laid, which had failed, these permanent mains were so different in the principles of construction that they would not fail. Whether they would or would not he (the speaker) did not know, nor would any one present be able to say until one process was gone through—that of putting them in the earth, covering them up, connecting them with the supply in houses, and turning the current on. Then if they had any weak places they would be revealed, just as the weak places were revealed in the mains which had failed. It was no good going on with the present mains up to anything like the tension that was necessary, and they had been obliged to cut their coat according to their cloth. Instead of sending 5,000 volts through them they had only sent through 2,500; even at that low tension they had served an exceedingly useful purpose to the Company as a sort of stop-gap, because, but for these mains, they could not have conducted their business in London even as they had done. They had thus settled the point that they could send current from Deptford to the Grosvenor Gallery in an instant of time, and in considerable quantity. He thought that the remarks of the Lord-Justice Clerk should be regarded by them as very consolatory.

The motion was unanimously adopted.

Resolutions were afterwards proposed declaring the dividend recommended on the Preference shares, re-electing the retiring Directors—the Earl of Crawford, Sir Coutts Lindsay, and Lord Wantage—and re-appointing the auditors, Messrs. Kemp, Ford, and Co.

A vote of thanks to the Chairman and Directors brought the proceedings to a close.

The following is Mr. S. Z. de Ferranti's report, referred to by the Chairman:—

"GENTLEMEN: I have the honour to report that during the past year the general works and buildings at your Deptford Station have been completed, and a large amount of machinery for supplying electric current has been erected. There is now in complete working order a plant consisting *of two* 30,000-*light dynamos*, with engines, boilers, and other accessories to correspond.

"In order to utilise this supply of current in London, mains were purchased and laid in the early part of last year, but I regret to say that some of them have proved a very great failure, owing to which you are not in a position to utilise more than one-quarter of the capacity of your Deptford plant. Had these mains succeeded you would now have been in a position to utilise the whole of the Deptford machinery above mentioned for the supply of the Corporation's customers in town.

"The Grosvenor central lighting station has continued to supply current to a large number of consumers during the past year, notwithstanding the

great difficulties attending its position in a most populous and busy district, where space and every other convenience are much limited. In order to use the plant of this station to its full advantage, and to secure the benefits of the riverside site, arrangements are now being made for its removal to Deptford, where, before the autumn, it will be in a position to contribute to the supply of light in London in a more economical and efficient manner than now. You will then possess plant capable of generating power for 90,000 lights, with which, after making most liberal allowances for reserve, you will be able to supply 60,000 lights simultaneously.

"In addition to the above, two large dynamos of the capacity of 200,000 lights each are being built. These machines will at first be used for 100,000 lights each, and the engines and boilers for this output are now completed, and the machines themselves are in a fairly advanced state, the heaviest and most difficult parts of them being well in hand. *It is expected that these machines will be completed about the end of the present year*, when the productive capacity of your plant will be raised to 290,000 lights, and allowing for reserve in accordance with the requirements of the Board of Trade, you will be able to supply some 160,000 lights simultaneously. At a later stage the current for 200,000 additional lights will be obtained from these machines by simply adding the necessary engine-power.

"The laying of distributing mains has been commenced and fair progress made in a portion of the Corporation's area. The manufacture of permanent trunk mains by the Corporation's own staff has been vigorously pushed forward, but partly on account of the time occupied in getting a new system into working order, and partly owing to the great difficulties experienced in meeting the varying requirements of the several local and other authorities, none have yet been laid. These mains have been tested on the Corporation's own premises, and the results show that they are capable of withstanding greatly more electrical pressure than will be required in ordinary working, and also that they are in every sense a practical and commercial success. The defective mains now in use between Deptford and London will shortly be replaced by these permanent trunk mains, when a supply of current to the full capacity of the machinery now erected at Deptford may be utilised.

"During the past year great difficulty has been experienced in obtaining a satisfactory meter for the registration of current supplied to customers, and this difficulty has entailed a certain amount of loss to the Corporation. Recently, however, several meters of a satisfactory type have been put into use, and now more than half the Corporation's customers are supplied through these meters. It is believed that before very long the Corporation will be able to supply all their customers by meter.

"It may be well here to remind the shareholders that in erecting its works at Deptford on a site immediately adjacent to the Thames, and upon a sufficiently comprehensive scale, the Corporation has taken its lesson from the gas companies. These companies commenced with small stations in the centre of populous districts, but experience has since shown that this was an undesirable method of proceeding, and that the true way to secure both economy and efficiency is to generate gas on a large scale on a commodious site at the water's edge, and at some distance from the district to be supplied. The Corporation has followed this eminently practical conclusion, and when the Deptford works are further advanced, the wisdom of following an example proved to be so successful in an enterprise of a kindred nature will be apparent."

Exeter Electric Light Company (Limited).

An extraordinary meeting of the shareholders of the Exeter Electric Light Company was held on Tuesday at the works in New York-road for the purpose of altering a resolution come to at the last meeting, fixing the number of Directors of the Company at seven.

Mr. W. H. ELLIS, Chairman of the Company, presided, and moved the resolution, which affirmed the desirability of raising the number of directors to 10.

Dr. WOODGATES, in seconding, referred to the progress which had been made in Exeter and elsewhere in the matter of electric lighting, and said that in every place in which it had been applied in Exeter it had given unqualified satisfaction, and it was shortly to be introduced into the Albert Memorial Museum. He also spoke of the great opposition which had been raised to it by interested parties, and trusted that the public would recognise its advantages, both from a sanitary and lighting point of view. About thirty years ago he remembered seeing the first introduction of the gas stick for lighting lamps, and it was not until last year that Exeter superseded the old ladders by its adoption, so that the city was thirty years behind the times in this direction. He did not think the citizens would care to be thirty years behind the times in the case of the electric light.

The resolution was carried unanimously, and Dr. Woodgates and Mr. J. Dalke were added to the list of Directors.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the Board of Directors of the Anglo-American Telegraph Company (Limited), held on Friday last, it was resolved to declare an interim dividend for the quarter ending March 31, 1890, of 12s. 6d. per cent. on the Ordinary Stock, and 25s. per cent. on the Preferred Stock, less income tax, payable on May 1st to the stockholders registered on the books of the Company on April 1, 1890

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended March 28th amounted to £4,558.

COMMERCIAL CABLE COMPANY.—This Company notify that they will pay a quarterly dividend of 1½ per cent. upon the outstanding stock on the 10th inst. to all stockholders of record on April 1st.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of March were £4,000, as compared with £4,540 in the corresponding month of last year. The receipts for the month of December, estimated at £3,000, realised £2,995.

DIRECT UNITED STATES CABLE COMPANY.—The Board of this Company have resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income tax, being at the rate of 3½ per cent. per annum for the quarter ending March 31, 1890, such dividend to be payable on and after April 24th next.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of March, 1890, amounted to £58,471, and to £55,987 in the corresponding period of 1889.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—Particulars will be found in our advertisement columns of the drawing of 305 Five per Cent. Australian Government Subsidy Debentures of £100 each. These Debentures will be paid off at par on July 1st next, at Messrs. Barclay, Bevan and Co.'s, 54, Lombard-street, E.C., after which date interest on them will cease.

GANZ AND CO.—A dividend of 70 florins per share has just been paid by this firm.

ORIENTAL TELEPHONE COMPANY (LIMITED).—The Directors of this Company yesterday resolved, subject to final audit of the accounts, to recommend to the shareholders a dividend of 3 per cent., free of income tax on the paid-up capital of the Company, other than the vendors' shares, for the year ended December 31st last, to place £2,000 to reserve, and write off £850 for depreciation, &c., the balance to be carried forward will be about £1,200.

SUBMARINE CABLES TRUST.—The Submarine Cables Trust announce that the coupon due in October last will be paid in full, on and after April 15th, by Messrs. Glyn, Mills and Co., of Lombard-street, E.C. The coupons should be left with the bankers for examination four clear days before payment. Certificate-holders have to present the coupons for October, 1889, only, and not those payable on April 15th next.

TELEPHONE COMPANY OF AUSTRIA.—This Company intimates that the usual half-yearly dividend to the 31st March on the Preference Shares at the rate of 6 per cent. per annum, payable, less income tax, early in April, has been declared by the Board.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended March 28th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,515.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month ended March 31st were £4,400.

WESTERN UNION TELEGRAPH COMPANY.—Mr. William Waldorf Astor has been elected to fill the vacancy in the directorate of this Company left vacant by the death of his father.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 621.—Vol. XXIV. FRIDAY, APRIL 11, 1890. Price Fourpence.

NOTES.

It is, perhaps, to be regretted that the points now in dispute between Prof. Forbes and Dr. Harries and Mr. Newman Lawrence were not more completely cleared up in the discussion at the Institute of Electrical Engineers. They are of some interest as bearing indirectly upon the danger respectively of alternating and continuous currents to human life. The authors of the Paper do not seem to have had this fact sufficiently in view, if, as stated by Mr. Lawrence, the Paper dealt "exclusively with phenomena after contact." Assuming, however, the contact to be momentary and equally good in each case, what we want to know is the relative physical effect of a continuous and alternating current of the same strength. A letter which appeared in *The Electrician* of January 25, 1889, may now be read with interest, since the writer draws from the fact that a slowly-alternating current is more painful than one which alternates more rapidly, an inference different from that to which Mr. Newman Lawrence seems to incline. The shocks being least bearable when slowest, argued "Telegraphist," it is the single sharp shock that hurts, if allowed to take full effect before reversal; and consequently a powerful stroke from a continuous current will do more harm than a rapidly-reversed current of like force. True, you may continue a comparatively weak alternate current till the resistance of the body is broken down, and the current becomes unbearable; but this is not the manner in which death is inflicted by electric lighting currents; nor is it proposed to be tried in that way on capital offenders at New York. In most cases where fatal results have ensued, the mischief was done at the moment of contact; and the writer of the letter above referred to is apparently of opinion that if he had to take the risk of a strong current through his body, he would rather "take it alternating."

Accumulators of the Planté type are now receiving a considerable amount of attention. M. Pollak has recently communicated to the *Comptes Rendus* some researches undertaken with the object of giving such cells a large capacity after a short time of forming. With this view plates are covered with spongy lead obtained electrolytically, and to ensure perfect adherence the plate surfaces are previously worked so as to present a brush-like appearance. The plate, after having been washed free from fatty matters, is coated with a paste of sulphate of lead and plunged into acidulated water between two plates of zinc. The forming is accomplished in 50 hours by passing the current through in one direction. The negative plates have then a greyish appearance, while the positives are deep brown. After the formation the adherence of the active material, consisting of spongy lead and binoxide of lead, is so good that the adhering surface of the superposed layer is indistinguishable. Such an accumulator, consisting of nine plates, four positives and five negatives, with a total weight of eleven kilogrammes, after 45 hours' forming, with a current of 16 amperes, gave, during a discharge kept constant at 18 amperes, a capacity of 95·4 ampere-hours. The initial potential was 2·12 volts, this falling slowly to 2 volts after four hours, and then more rapidly to 1·8 volts after a little over five hours. The same accumulator recharged with a current of 16 amperes for seven hours gave during the discharge 102·3 ampere hours, showing an efficiency of 91·4 per cent. and a capacity of 9·13 ampere-hours per kilogramme of lead. This capacity does not compare unfavourably with that of cells of the E.P.S. type; and if such cells are durable there should be a future for them. It is, however, impossible to test the efficiency of secondary batteries from a single charge and discharge; and, moreover, the watt-hour should be taken as the unit of measurement, since very anomalous results may be obtained from estimating the ampere-hour efficiency.

Observations on the ratio of luminous to non-luminous radiation emitted by various sources of light are of some interest to electricians, as, even in the arc lamp, which is far more efficient than any other light, the proportion is very small, and it is thus possible, theoretically, to greatly improve existing methods of lighting. It is known from experiments of Prof. Nichols that for the arc lamp only about 10 per cent. of the radiated energy is luminous, while, for the incandescent lamp, the ratio is 5 per cent.; and, according to Thomsen, the proportion for the candle, the oil lamp, and the gas flame is about 2 per cent. each. Experimental determination of the ratio is, however, difficult, and different authorities give very varying results. The radiation emitted from an Argand gas burner has recently formed the subject of careful research by Sir John Conroy, a description of whose experiments appears in the February number of the *Proceedings* of the Royal Society.

The radiation emitted by the Argand flame was allowed to fall on the face of a thermopile, either directly or after passing through different thicknesses of water or alum solution, contained in a cell with glass ends. In the former case the whole energy was measured, while, in the latter, only those rays affected the thermopile which were unabsorbed by the

Digitized by Google

liquid cell. In some preliminary experiments it was shown that there was no measurable difference between the absorbing power of water and alum solution, and that when the length of the liquid was 15 cm., or more, the transmitted radiation consisted almost entirely of light rays. The result obtained by Sir JOHN CONROY was that the radiation from an Argand gas burner consisted of 1·75 per cent. luminous and 98·25 per cent. non-luminous radiation.

THE American telegraphic journals are now discussing the widespread discontent which is manifesting itself among the telegraph operators in the United States, and speak of the possibility of a great strike. Curiously enough, the low rate of wages and long hours prevalent in that country, and the consequent discontent, are due to there being a glut of competent operators out of employment, owing to the amalgamation of the companies and the absence of sharp competition. The attractions of telegraph employment in recent years have resulted in the training of more telegraphists by far than can get situations. It is to be hoped they may find employment of another kind. Until then, the working telegraphists had better think twice before they strike, and change places with their less fortunate brethren.

MR. GRAFF BAKER'S letter in the *Financial News* of Tuesday is a mere re-echo of the leading article on the subject of electric traction which appeared last week in that journal. The communication is mainly devoted to retailing once again the oft-told story of the rise and progress of electric traction in the United States. All that Mr. BAKER, after nearly twelve months' active work, is able to tell us with regard to electric traction in Great Britain is that "A company is in progress of formation which will materially assist the introduction of electricity in the place of steam as well as horses. This company, when ready for business, will be prepared to put down the necessary plant and equipment for the operation of any given road, and to furnish the power at a price per car mile, varying according to conditions, never to exceed the present cost of working, whether by steam or horses; and, should electrical traction become as popular on this side as it has already in the States, I should not be surprised to see the profits of this company exceed those of our own (the Thomson-Houston International Electric Company)." Up to the present, this process of company formation has in this country exhausted most of our energy—and money.

Now that electricity and its varied industrial applications have become a stock subject for popular articles in the monthly magazines, it is certainly satisfactory to find that the writing of these educational disquisitions is being more and more confided to those who know what they are writing about. Amongst other articles in the magazines for the current month is one in *Scribner's* by Mr. JOSEPH WETZLER, on "The Electric Railway of To-day;" and another by Mr. A. A. CAMPBELL SWINTON on "The Present Position of Electric Lighting," which appears in *Murray's*. Mr. WETZLER'S is one of the best popular articles on electric traction that we have seen. A perusal of it would, perhaps, tend to remove any doubts that may linger in the minds of our tramway magnates as to the capabilities of electricity, though we are afraid that the aerial spider's webs shown in several illustrations would tend to counteract the persuasive effect of the 210 per cent. net increase in the earnings of the tramway at Davenport, Ia., which it is affirmed resulted from the adoption of electric traction. Mr. SWINTON confines himself to a plain and business-like exposition of the cost of electrical installations. He points out at the conclusion of his article that any great reduction in the present price of electricity, apart from the increased economy consequent upon large-scale working, must be looked for in the direction of cheaper, more durable, and more efficient glow-lamps.

"A WORD is urgently required for immediate use," Lord BURY tells us, in the *Times* of Wednesday, "which shall express progression by electric power." The result of this appeal to the ingenuity of the word-coining fraternity has been a column and a half of more or less cacophonous suggestions in yesterday's *Times*. To "mote," "motor," "electrize," "electrate," "volize," "amber," "tric," and "squirm" are a few of the monstrosities proposed; and in our own correspondence columns will be found a letter from Mr. O. C. D. ROSS, urging the claims of the verb "to faradate." For our own part, we shall be content to wait indefinitely for the word if only we obtain the thing itself.

Edinburgh Exhibition.—Mr. A. R. Bennett has been elected a Vice-Chairman of the Executive Council of the Exhibition.

Carlisle.—The Brush Electrical Engineering Company have abandoned their Provisional Order to enable them to light this city by electricity.

Ipswich.—The Town Council has given consent to the Provisional Order of the Brush Electrical Engineering Company, a draft of which had already been approved by the Council.

Incandescent Lamp Manufacture.—A company has been formed at Birmensdorf, with a capital of 250,000fr., under the title of the Zurich Incandescent Lamp Company, for the manufacture of glow lamps.

Society of Engineers.—Amongst the recently elected honorary members of the Society of Engineers are:—Lord Armstrong, Sir Benjamin Baker, Sir James Douglas, Sir William Thomson, and Mr. William Anderson.

Electric Traction in Germany.—From the *Elektrotechnische Echo* we learn that the Deutsche Strassenbahn-Gesellschaft intend to introduce electric traction on their lines, but have not yet decided on the system to be adopted.

Brussels.—The Société l'Électrique have just fitted the Palace of the Comte de Flandre with an installation of 900 lights. The lamps are run off Julien accumulators. The number of lights is shortly to be increased to 1,500.

Telephonic Extensions.—Two new trunk wires between Dundee and Forfar have just been completed, and the trunk wires for Brechin, Montrose, and Aberdeen are almost finished on the section between Dundee and Forfar.

Bath.—On Saturday last the final trial run of the machinery and engines at the Electric Light Works took place; and this week the lighting of the various shops, hotels, and private houses where the fittings are completed commenced.

University College, Bristol.—The third term of this College commences on April 29th. A course on electrical engineering, comprising electric lighting, dynamo-electric machinery, and transmission of power, will be held during this term.

Digitized by Google

Galway.—The Galway Harbour Commissioners have accepted the tender of the Galway Electric Company to light the old and new docks with electric light. The water-power of the Corrib River is being utilised for the production of the electric light.

The International Telegraph Congress.—The International Telegraph Congress is to open in Paris on May 15th. It will be held, says the *Times*, in the Prince Imperial's riding hall at the Louvre, and the work of clearing out the hall and preparing it for the Congress has begun.

Electroculture.—A report on the subject of electroculture was presented to the sixth Congress of Russian Naturalists, by M. Specnew. There was considerable proof, he said, that the use of electricity reduced the diseases of plants caused by micro-organisms to a minimum.

Electrical Installation Regulations in Spain.—A royal decree, dated 14th March last, has been issued by the Spanish Colonial Minister, establishing the conditions relating to electrical installations. The full text of the decree is given in the *Industria é Invenciones* of April 5th.

The Popp System.—According to the *Electrotechnische Zeitschrift* tests of the Popp system will be conducted at the Frankfort Exhibition. The above-named paper maintains that the efficiency of the system is only 15 per cent.; but Mr. Popp, in a letter to the *Finanz Herald*, asserts that it is 75 per cent.

National Telephone Electrical Society.—On March 21st Mr. A. H. Church read before this Society a Paper on "Telephony Abroad," in which he treated at length the Van-Ryssel-berghe system and duplex telephony. On the 28th Mr. W. A. Baxter read a Paper on "Inspection of Telephone Instruments."

A Correction.—Our Boston contemporary *Modern Light and Heat* is good enough to point out that on page 473 of our issue of March 14th, by a slip of the pen, we attributed Prof. Elihu Thomson's recent Paper on "Safety and Safety Devices in Electric Installations" to his well-known coadjutor Prof. Houston.

Society of Arts.—Amongst the Papers for the Wednesday evening meetings to the end of the Session are the following: May 7, "The Aim and Scope of Higher Technical Teaching," by Dr. Percy F. Frankland; May 14, "Professor Elihu Thomson's Electro-Magnetic Induction Experiments," by Dr. J. A. Fleming.

Royal Institution.—At the last general monthly meeting of the Royal Institution Major-General C. E. Webber, C.B., was elected a member. The special thanks of the members were returned for the following donations to the fund for the Promotion of Experimental Research:—Ludwig Mond, Esq., £100; Lachlan M. Rate, Esq., £50.

The United States Postal Telegraph Bill.—Mr. J. M. Seymour, a member of the New York Stock Exchange, has, says the *Financial News*, informed the Congressional Committee on Post Offices that he is prepared to establish a postal telegraph at the terms and rates proposed in the Postmaster-General's Bill, or a uniform rate of 25 cents per message.

Craiova (Roumania).—The firm of Egger and Co., of Vienna, are negotiating for the lighting of Craiova by electricity. They seek a 45 years' concession, and propose to charge 4 centimes per 16 candle-power lamp-hour to the municipality, and 6 centimes to the public. The municipality promise to take up 800 lamps, and the scheme is now before the Roumanian Parliament.

Electrical Competitions.—The following electrical competitions are announced for this year by the Société d'Encouragement:—The Melsens prize of 500fr., to be awarded for an application of chemistry or physics to electricity; a prize of 3,000fr., for a method of transporting natural energy to a distance; a prize of 2,000fr., for a commercial method of preparing ozone, and for making practical use of it.

The Electric Light on the Warship "Le Hoche."—The electrical installation on board the French battleship "Le Hoche" comprises 4 14-unit (70 volts × 200 amperes) Desroziers' dynamos, running at 350 revolutions, driven by Breguet compound engines, through Raffard elastic coupling. The lights comprise 6 projectors, taking from 65 to 75 amperes, and 14 50-candle-power, 23 32-candle-power, and 350 10-candle-power 65-volt incandescents.

Abandonment of Metropolitan Electric Lighting Schemes.—The following Electric Lighting Orders will not be proceeded with:—St. Martin's-in-the-Fields and Strand; St. Margaret and St. John the Evangelist, Westminster; City of Westminster Electrical Syndicate; St. Pancras Electric Supply. The first-named Order was applied for by Messrs. Gatti; the second, by Messrs. Renshaw, King, and Co.; the other two by the syndicate named, and by the House-to-House Company.

Bradford Scientific Association.—At the last meeting of this Association a Paper was read by Mr. Sydney Baynes, A.I.E.E., Managing Engineer of the Bradford Corporation Electric Light Department, on the "Progress of Electric Lighting." The lecturer described the gradual development of the dynamo, arc and incandescent lamps; and in the course of his remarks briefly touched upon the leading central stations at home and abroad. Diagrams and apparatus were used to more fully illustrate several points connected with electrical progress.

St. George's (Hanover-square) Vestry.—At its last meeting this Vestry sanctioned the laying of electric mains by the Westminster Electric Supply Corporation under the footways, upon condition that if any of the inhabitants in front of whose property the lines are laid obtain the sanction of the Vestry for the construction of vaults under the footway, the Corporation shall, after one month's notice from such inhabitant, remove the main into the carriage-way to enable the vault to be constructed, and that in future similar applications be granted subject to a similar condition.

The London Subways and Overhead Wires Bill.—At the last meeting of the London County Council the Parliamentary Committee reported that in concert with the Highways Committee they had considered the thirty-seven petitions presented against this Bill, and that, having regard to the attitude of uncompromising opposition to the project taken up by so many of the companies, they recommended that the Bill should not be proceeded with this Session. They recommended, however, that the part of the Bill which relates to overhead wires should be proceeded with. The recommendations were agreed to.

Social Gathering of Yorkshire Telephonists.—On Friday evening, March 21st, the staffs of the various centres in the Yorkshire District of the National Telephone Company assembled to spend a social evening at St. James's Hall, Leeds. Previous to the gathering a gold watch was presented to Mr. J. C. Chambers, late General Manager for the Yorkshire District, by Mr. James Holroyd, of Halifax, on behalf of the united staffs, as a token of the high esteem in which he was held by them during the many years of his connection with the district. Mr. Chambers has recently removed into the Lancashire district.

Beckenham Local Board.—The representatives of the Local Board had a conference a few days ago with the Board of Trade and the promoters of the Crystal Palace District Electric Lighting Order; and a satisfactory arrangement was come to, with the exception of one of the clauses which had reference to the transferring of the Order. The Board of Trade absolutely prohibited the assignment of the Order. Upon the question of purchase it was finally agreed that a clause should be inserted by which the Beckenham Local Board will have the right of purchase after a period of seven years and within fifteen years by paying 33 per cent. in addition to the capital actually expended on the undertaking, the power of purchase being entirely at the option of the Board.

Exports of Telegraphic Wires, &c.—The Board of Trade returns, issued on Wednesday, give the totals of the exports of telegraphic wires and apparatus connected therewith for the first quarter of the current year. Up to the end of February last this year's exports had shown a decided improvement; but, owing to very large shipments in March last year, the quarter's

Digitized by Google

figures do not compare quite so favourably. The following is a comparative statement of the monthly exports during the first quarter of the current and two previous years :—

	1890.	1889.	1888.
January	£71,686	£113,230	£41,231
February	201,594	32,086	14,051
March	51,390	285,993	32,795
	£324,670	£431,309	£88,077

Electrical Apparatus for the Transvaal.—We announced some time ago that a large installation for the electric transmission of power was being manufactured by the Sprague Company for the Forbes Reef Gold Mining Company of South Africa. The Forbes Company are now so satisfied that electricity is the most convenient and economical agent for transmitting power over long distances, and applying it at its point of use, that the managers of that Company have ordered additional apparatus for the transmission of 75 more horse-power. This will make a total of 215 horse-power to be transmitted. The efficiency of the whole system will, it is said, be about 70 per cent.. Part of the apparatus has already been shipped to the Transvaal. When this is finished it will be one of the largest electric mining transmission plants in the world.

The Electric Light in Military Operations.—In a recent Paper, read before the Société d'Encouragement M. Lemonnier stated that when beams of light from the Mangin projectors on the top of the Eiffel Tower were thrown in the direction of the Sèvres Valley, observers placed at a distance of 2,000 metres from the spots illuminated by the rays were able to clearly distinguish small objects, such as animals and human beings; even when the illuminated region was 10,000 to 11,000 metres ($6\frac{1}{4}$ to $6\frac{3}{4}$ miles) from the source of light. M. Lemonnier then pointed out the great importance of these facts in connection with the defence of entrenched positions and fortified towns, and said it was the opinion of many military officers that the use of noiseless and smokeless powders would increase the tendency to night attacks. The Parsons turbo-dynamo had, he said, made available a very suitable means of generating electricity for military purposes.

Electricity and the Mariner's Compass. — Lieut. W. H. Schuetze, the superintendent of compasses of the United States Navy, is led to believe, from observations on board steel vessels that no reliable compass data can be gathered unless the vessel is in dry dock. It has been the practice to undertake these observations while the vessel is in the water; but, under these circumstances, it always has more or less motion, which seriously affects the results. The deflections produced on compass needles by the dynamos used for electric lighting are, he reports, in some cases, as much as 2deg.; and the superintendent recommends that the position of the dynamos should be a secondary consideration to that of the compasses. About 40ft. has been considered a safe distance between dynamos and compasses; but in determining this question the induction of magnetism in bulkheads and other vertical as well as horizontal steel and iron must not, Lieut. Schuetze remarks, be overlooked.

Marylebone Vestry.—At a meeting of this vestry last week the Works Committee recommended, as to a communication received from the Metropolitan Electric Supply Company, giving notice of the Company's intention to lay cables connecting Rathbone-place generating station with the Manchester-square station, "That the Vestry permit the work to proceed at once, provided the Company agree to remove their pipes at the Company's expense, where any owner wishes to reconstruct his vaults." This was opposed by Sir Edwin Galsworthy, who moved as an amendment, "That the Vestry object to the work proceeding unless the Company agree to abide by the resolution passed by the Vestry on the 6th ult.," which was to the effect that "in the event of any owner of property wishing to construct cellars or vaults under the footway, the Company shall remove their mains, at their own cost, within six weeks of any such notice, into the carriage-way." This amendment was put to a division, and, finally being carried, became the substantive motion, and was agreed to.

The Electric Launches at the Edinburgh Exhibition.—The four launches which will run in the canal at Edinburgh are designed by Messrs. Morton and Williamson, and built by T. B. Seath and Co., Glasgow. They are 40ft. long, 6ft. 6in. wide, and draw 2ft. 1in. They have a carrying capacity of 40 passengers. The electrical equipment has been supplied by Messrs. Immisch and Co., and is similar to that used on the Thames launches. The charging plant will consist of a 25 horse-power engine and an Immisch dynamo, with suitable switch arrangements for charging four launches at the same time. The motors are capable of an output of about $3\frac{1}{2}$ brake horse-power, at 800 revolutions per minute. The propellers are coupled direct to the motor shafts. A ball-bearing thrust-bearing is attached to the motor-bed, and is constructed in combination with the plain bearing of the motor. This arrangement is the invention of Messrs. Immisch and Co., and has been patented by them. By its use the friction is reduced to the minimum, and there is no noise or vibration. The high-speed propellers have been made after a careful course of experiments, and give the highest efficiency hitherto attained with such small blades. They are designed for going both ahead and astern. The steering, starting, and reversing gear are so arranged that one man has the launch entirely under control.

The Electrical and Magnetic Disturbances at the Paris Observatory.—The efforts of the Director of the Paris Observatory to modify the direction of the proposed extension of the Sceaux line have, says *La Lumière Electrique*, made public some very curious phenomena. The Observatory is situated between two busy suburban lines, namely, the Chemin de Ceinture, which is only 60 metres away, and the Sceaux railway, which is 80 metres distant. The passage of the Ceinture trains causes the bifilar magnetometer needles to oscillate so violently and distinctly that M. Descrois, of the Observatory staff, is in a position to supply the railway company with a sheet checking the time of their trains. The curve of the declination needle, curiously enough, exhibits no traces of disturbance. The bifilar needle is kept by torsion at right angles to the magnetic meridian, and therefore parallel to the motion of the Ceinture trains; and M. Descrois is inclined to think that the observed disturbance is due to the fact that the wheels and axles become strongly magnetised, owing to their movement in the magnetic meridian. The Sceaux trains have no effect on the magnetometer needles; but give rise on the other hand to marked disturbance of the registering electrometers. The station on this line is at a distance of about 100 metres from the Observatory, and whenever the driver lets off steam the electrometer partially discharges, and then immediately afterwards again rises to its normal potential. This singular phenomenon takes place no matter what the potential of the atmosphere may happen to be.

An Erratic Lightning Flash.—During a thunderstorm at Larnaca the entrance door of a house occupied by one of the Eastern Telegraph Company's *employés* was struck by lightning. The woodwork round the iron lock on the inside of the door and down to the top step of a flight of stone steps was completely splintered, and the lock was almost wrenched from the woodwork. Attached to the outside wall of the house was an iron stove-pipe, reaching considerably above the roof. No trace whatever could be found of this having been touched, and nothing inside or outside of the house showed any sign of an electrical discharge except the door. Within a stone's throw of the house in question are the buildings of the Anglo-Egyptian Bank, with a lightning rod of considerable altitude; also, quite close, are several high consular flagstaffs. None of these were touched. In the immediate vicinity are several iron telegraph poles, with lightning rods attached, and not far distant are several mosque minarets of great height, with metal caps. None of these were touched. It is difficult to understand, on the principle of the "protected area," why the flash struck the door almost on a level with the street instead of the iron stove-pipe, or the adjacent lightning rod, or the flagstaffs, telegraph poles, or minarets; or why it did not make direct earth in the muddy and flooded street within a few feet of the wooden door? Again, the houses adjoining and on the opposite side of the street—a narrow one—are built of sun-dried mud bricks, and these were saturated with rain, making capital earth; yet they escaped. The house of which the door was struck is built of trimmed blocks of stone.

MAGNETISM IN IRON AND OTHER METALS.*—XIII.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 545.*)

§ 61. **Example of the Ballistic Method.**—In the following example† the specimen was a ring welded out of a piece of moderately soft annealed iron wire :—

Diameter of wire forming the ring.....	0·248 cms.
Area of section of iron.....	=0·0483 sq. cms.
Mean radius of ring 5·0cms.	Mean circumference 31·4cms.
Number of turns in magnetising coil...	474
Number of turns in secondary coil.....	167
Area of earth-coil	1216 sq. cms.
Number of turns in earth-coil.....	10
Earth's force, cut by earth-coil	0·34
Ballistic throw on turning over earth-coil	42·9 scale div.

The mean value of the magnetic force per ampere was, therefore :—

$$\frac{4\pi \times 474}{10 \times 31{\cdot}4} \text{ or } \frac{2 \times 474}{10 \times 5{\cdot}0} = 18{\cdot}96.$$

The resistance of the secondary circuit was not altered throughout the experiment, and the correction for air-space within the secondary coil was negligible. Hence, from the above data, the change of the induction **B** per square cm. in the iron corresponding to one scale division of ballistic throw was—

$$\frac{1216 \times 10 \times 0{\cdot}34 \times 2}{0{\cdot}0483 \times 167 \times 42{\cdot}9} = 23{\cdot}89.$$

The experiment consisted in applying first a weak magnetic force, and increasing it by a series of sudden steps to 9·14 C.-G.-S. units, and then removing and finally re-applying the same force, all by steps, while the ballistic throws were observed. The following Table III. gives the results, μ, **I**, and κ having been calculated from **B** and **H**.

TABLE III.

H.	Ballistic Throw.	Sum of Throws.	B.	μ.	I.	κ.
0·13	1·1	1·1	26	...	2	...
0·26	1·1	2·2	53	...	4	...

8·00	14 5	510·9	12,170	...	971	...
9·14	10	520·9	12,440	...	990	...

The relation of **B** to **H** in this experiment is shown in Fig. 29. It will be seen that the curve of magnetisation presents the same characteristics as in the former example. The residual value of **B** is 88 per cent. of the induced value.

* All rights are reserved.

† *Phil. Trans.*, 1885, pp. 530-532.

§ 62. **Ballistic Method using Reversals : Magnetisation of an Iron Ring (Rowland).**—A few more examples may be quoted in further illustration of the relation of magnetisation to magnetising force in iron.

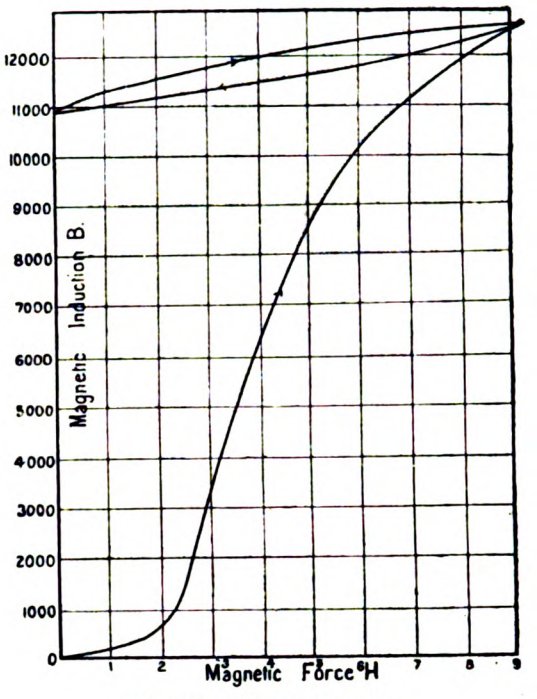

FIG. 29.—Wrought-Iron Ring.

In the following experiment by Rowland* the specimen was a welded and annealed ring of "Burden's Best" wrought iron, 6·77cm. in mean diameter and 0·916 sq. cm. in section. **B** was measured by reversing the magnetising current and taking half the ballistic effect. The ballistic effect of breaking the magnetising current was also noted. This, subtracted from half the effect of reversal, gave the residual magnetism at each stage in the magnetising process. The results, reduced to C.-G.-S. units, are given in Table IV.,† where the residual values of the magnetic induction appear in the third column under the heading B_r.

TABLE IV.

H	B	B_r	μ
·18	71	18	390
·69	600	211	869
·86	967	439	1,129
1·27	2,460	1,570	1,936
1·41	2,920	1,940	2,078
1·45	3,080	2,060	2,124
2 04	4,960	3,630	2,433

17·69	14,540	7,990	824
34·17	15,770	8,130	462
46·02	16,270	7,850	354
64·33	16,600	7,890	258

* *Phil. Mag.*, Vol. XLVI., 1873, p. 151.

† The dimensions of **H** and of **B** and of **I** are $\frac{(\text{Mass})^{\frac{1}{2}}}{(\text{Length})^{\frac{1}{2}}\,(\text{Time})}$. Rowland, in the Paper cited, uses *metre*-gramme-second units in expressing the induction. His numbers (called Q in the Paper) have therefore to be divided by 10 to bring them to C.-G.-S. units. With regard to **H**, he gives (under the heading M) numbers which are equal to the magnetic force divided by 4π. These have accordingly to be multiplied by $\frac{4\pi}{10}$ to reduce them to C.-G.-S. units of **H**.

Digitized by Google

Fig. 30 shows these values of **B** and $\mathbf{B}_r$ in relation to **H**, for forces up to 10 C.-G.-S. Beyond that force, the residual magnetism becomes very nearly constant. The proportion of residual to induced magnetism is considerably smaller here

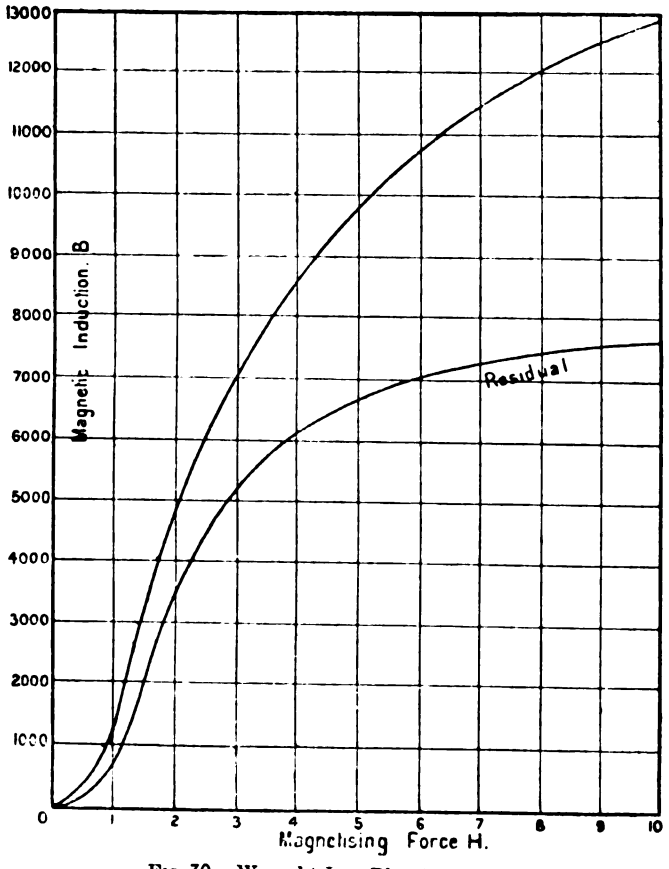

Fig. 30.—Wrought-Iron Ring (Rowland).

than in experiments with long wires or with wires welded into rings. Probably this is due less to any specific difference in the material than to a difference in the conditions of the experiment. It was shown long ago by Von Waltenhofen that when magnetic force is suddenly removed from an iron rod it leaves less residual magnetism than when gradually removed.* This is notably the case when the specimen is comparatively thick. In a thick rod or ring the sudden with-

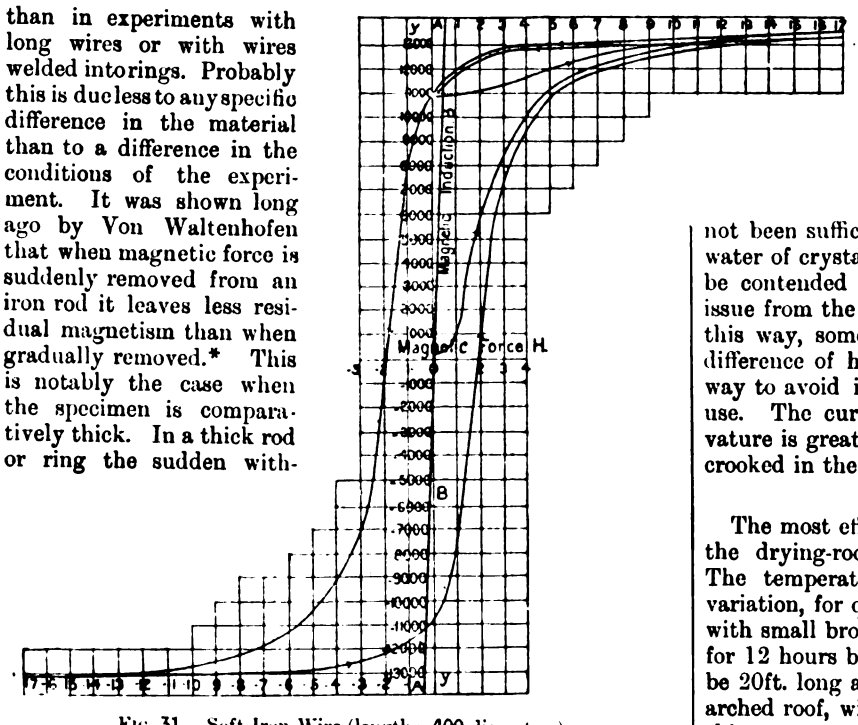

Fig. 31.—Soft Iron Wire (length = 400 diameters).

drawal of magnetic force sets up oscillating circumferential currents in the substance of the metal, which have an effect not unlike that which is produced in the process of "demagnetising by reversals" (§ 42). With very long wires or rings of small section one commonly finds 80 or 90 per cent. of the induced magnetism survive the removal of magnetising force, especially when the force is reduced by small steps or quite continuously. In the present case the force was removed suddenly, and the ring was thick.

§ 63. **Cyclic Process of Magnetisation: Long Iron Wire.**—In this instance the specimen—a straight wire of very soft annealed iron, 0·158 cms. in diameter and 64 cms., or 400 diameters, long—was tested by the step-by-step ballistic method,* the magnetic force being first raised from zero to 17·26 units, then reversed to −17·26, then reversed again to +17·26, then reduced to zero, and finally restored to +17·26. The effect of these cyclic processes are exhibited in Fig. 31 sufficiently to make it unnecessary to quote the numerical values of **B** and **H**. At the beginning the wire had a small amount of initial magnetism, which was found by slipping off the secondary coil.

In this figure the magnetising force of the solenoid is accepted as the whole magnetic force **H**, no correction having been made for the influence of the ends. If we treat the rod as equivalent to an ellipsoid 400 diameters long, **H** is to be measured from the line O A instead of from O Y.†

On both sides of the figure the residual magnetism is 82 per cent. of the induced, and the reversed magnetic force required to remove it—the "Coercive Force," § 47—is 1·9. This figure is thoroughly typical of the behaviour of soft wrought iron when subjected to cyclic reversals of magnetic force.

(To be continued.)

ELECTRIC ARC LIGHT CARBONS.

BY O. G. PRITCHARD.

(Continued from page 546.)

Prior to the discovery of the cause of the lateral fissures referred to at the close of my last Paper, I conceived it possible that this fault might have its origin in the speed of the hydraulic pump. This does not, however, appear to affect the carbons, although a speed of about 40 revolutions per minute would seem sufficient. The second fault we may have to contend with is the sudden appearance of longitudinal fissures, increasing, both in depth and width, a few hours after the carbons have been placed in the drying-room. This is due to the fact that the caramel has not been sufficiently carbonised, and still retains some of the water of crystallisation. The third and last fault which has to be contended with is the curving of the carbon rods as they issue from the press; sometimes only a few carbons are affected this way, sometimes many. It must be caused, I think, by a difference of hardness in the pugged stuff, and, if so, the best way to avoid it will be to have the stuff repugged just before use. The curved carbons must be rejected, whether the curvature is great or small. A curved carbon will aways come out crooked in the firing.

Drying-Rooms.

The most efficient and certainly the cheapest way of heating the drying-rooms is by means of the slow-combustion stove. The temperature can then be maintained, without sensible variation, for quite six hours, if the fires are carefully built up with small broken coke, and without renewal ought to burn for 12 hours before extinction. The first drying-room should be 20ft. long and 8ft. wide, and 8ft. to the springing of the arched roof, with the stove in one corner nearest the door. By this arrangement the furthest end of the room is only slightly heated, whilst increased heat obtains near the stove Fig. 7 is a ground plan of the first drying-room. A is an iron sliding

† By the table in § 33, the value of $\frac{N}{4\pi}$ for an ellipsoid 400 diameters long is 0·000037. Hence the line O A is drawn at such an inclination as to make the reaction of this upon the field equal to a force of 0·37 when B is 10,000.

Digitized by Google

door, B C D the shelving, framed and built up with angle iron, as already described. At the end E (Fig. 8), and on the lower shelf the temperature will remain nearly constant at about 75° F., while the temperature at G will be about 110deg.; at H, nearer the stove, the temperature will be 120deg., and at F, 140° F. These temperatures will always bear a relative proportion to each other, and never vary much.

The carbons are first placed on the shelves at E, removed to G, and after 36 hours to F, where they remain for 12 hours; afterwards removed to the second drying-room and kept for two days at a temperature between 180deg. and 200deg. This drying-room should be much smaller (about 10ft by 8ft.), after which the carbons should be ready for firing. They ought not to be indiscriminately taken, but should be separately handled, as some of the interior carbons may not be sufficiently dry. Their condition is best ascertained by trying to bend them; if they feel the least inclined to bend they are unfit, and must remain until they are fit. Firing before fitness means breakage.

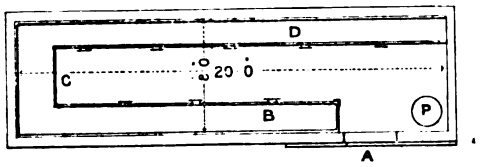

Fig. 7.—First Drying-room (Ground Plan).

I now describe my method of building the kilns. A cleanly but costly system has been tried, but not generally adopted, I believe, of firing carbons by means of gas and atmospheric air combined. The system may be good, but the expense appears to me to be too great. My system is to lay firebrick on the flat, and well grouted with cement; upon which build the two long sides of the kiln B B (Fig. 9), with bricks on edge, well laid in cement, composed of three parts of Stourbridge clay and one part iron grindings. The sludge arising from the grindstone, well mixed, forms a valuable cement, and will not crack under extreme heat. A crack in the kiln admits air, and disintegrates the carbons. The short ends of the kiln are built with bricks on the flat, A A (Fig. 9); the thicker the ends are the better, but 4½in. are sufficient. The kiln must be 2in. longer than the width of two of the plates, and 2in. wider than the length of the plates, which should be 2in. longer than the carbons. This allows for filling in with sieved ashes, which should be kept perfectly dry; any trace of moisture will show itself in the practical disintegration of the carbons.

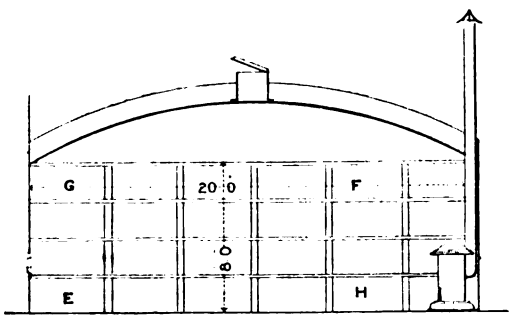

Fig. 8.—First Drying room (Section and Elevation).

The lines at C C (Fig. 9) show the direction in which the carbons are to be packed. The ends A A are made thick to avoid any lateral heat; the fires being made at D D tend to keep the carbon straight. Any heat in the direction of A A would inevitably twist them. After the kilns are packed and covered over to a depth of 2in. with the ashes, the surface had better be covered with a sheet of tin, and built in with firebricks, well filled in between the joints with the prepared cement, and pointed before using the kilns. After construction a fire should be made in and around the kiln, so that it may be perfectly dry when used. The trays in which the carbons are fired must be kept solely for that purpose. The furnace consists of a ring of firebricks, built as shown at E E E E (Fig. 9), with interstices between them of about 2in., E E. (Fig. 10), This circular wall should impinge upon the kiln at F F (Fig. 9), to keep the heat from the sides A A. The bricks are laid loose without cement, and are built to the height of the kiln. The fires must be lighted at D D, gradually adding coke as the fire advances, eventually increasing the height of the walls about a foot higher than the kiln. If the fire was lighted the first thing in the morning, it should not be piled over the top until the evening, and this done only by covering with coke and banking over with cinders and clay. Allow this fire to die out, when

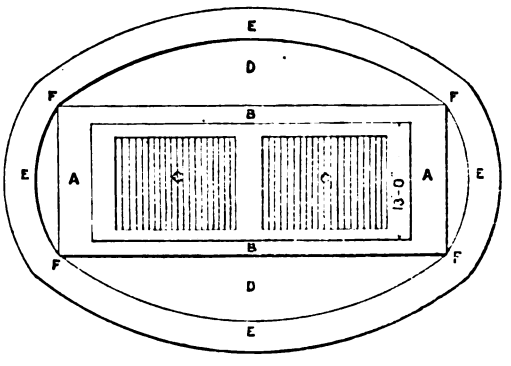

Fig. 9.—Kiln (Ground Plan).

the carbons will be found, on opening, when cold, sufficiently carbonised for the after-process.

The second or final firing has for its object the contraction of the carbon molecules, and increase in density and conductivity. The first firing, however, must be sufficiently prolonged to effect the carbonisation of the caramel, otherwise when placed in the hot saturating bath the carbons would become partially disintegrated. The second firing should be conducted as follows: Bank up as before mentioned in the evening; on the following morning rake out the lower holes all round, and keep a strong fire all day all over the kiln. Bank up partially in the evening, and more completely the following morning. Three days after, on opening, the kiln will be found at a white heat. When it is desired to withdraw the carbons, pull down the retaining wall, and clear away the fire and accumulated ashes, and expose the kiln to the air. Do not open before you can bear your hand on the outside. The top bricks may be taken off, and the kiln emptied, if the carbons are not too hot to hold. I should mention that straight carbons will twist if exposed to the air hot from the kiln; but if once allowed to cool, no after-firing has the least effect upon them. This form of kiln gives out an intensity of heat sufficient to melt wrought-iron, is very easily regulated and modified by blocking up more or less the interstices, and the firing can be prolonged for any length of time by banking up with brick clay, which in itself partakes of the nature of a slow-burning fuel.

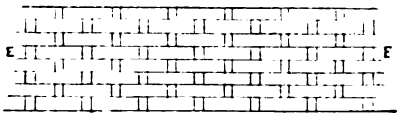

Fig. 10.—Brick wall of Furnace.

The condition of the carbons as they leave the kiln may, in some measure, be determined by the sound emitted when struck one upon another. This sound should be distinctly metallic, the more so the better. This metallic ring increases in the finished carbon to the clearness of a small silver bell; it is only heard in good carbons. A carbon, however, is not necessarily perfect, although the ring may be perfect. It is very desirable to know in what condition the carbon leaves the kiln, to be able to determine what it lacks, and what it requires to perfect it. The feebleness of its metallic ring will indicate that it is soft. If you insert the end of one of these carbons

Digitized by Google

in a clear hot fire until it is red hot, and on taking it ont observe it closely, you will find it smoulder for quite five minutes before it dies out. If you scrape this end with a knife, much carbon powder will detach itself. Observe also the colour of the powder; if reddish, the carbon is impure. The colour of the burnt part of a good carbon is a bluish steel-grey. This holds good for all the best foreign carbons. If the carbon just taken from the kiln had been put in circuit, the current would have made it red hot from end to end, but no arc would have formed for want of conductivity. By imparting increased density to the carbons, these symptoms of an unfinished carbon are altered, and give place to easily recognised signs, which are always the characteristics of a good finished carbon, viz., rapid extinction of the heat after firing the end, and hardness of surface, which becomes as hard as a rod of iron, and does not allow of the surface being disturbed or injured by scraping.

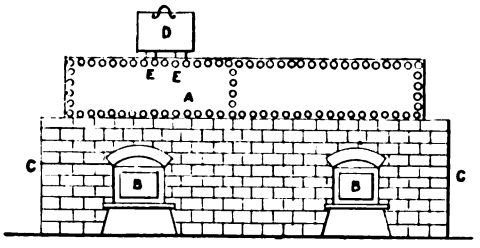

Fig. 11.—Saturating Tank.

Now, to effect this change, the carbons must be saturated, and the operation is carried out as follows:—An iron tank, A, (Fig. 11) is provided, partitioned off at one end to contain hot water, and the tank is placed upon a range, with two fireplaces, B B. Fires being lighted, the tank must be filled to the depth of 12in. with water and a sufficient quantity of sugar to form a syrup. The boxes, D, constructed of tin or zinc, with perforated bottoms, are filled with the carbons packed vertically, and placed in the tank. After boiling half an hour the boxes are removed, and placed upon iron bars, E E, to drain. When cold replace them in the tank, and repeat the process three or four times. Drain them well, and wash the carbons freely in the hot-water end. Remove them when cold (by which the liquor is drawn into the centre) into the third drying-room, and keep them there for 24 hours at a temperature of between 180° and 200° F., after which the whole process may be repeated until the carbons show the characteristics described above of a finished carbon.

Numerous experiments on the different modes of coring enable me to say that the method of coring is of less importance than the condition of the material. A hard core is useless. The best possible form is that of a compressed powder, breaking up easily with the point of a knife; but if too softly packed the current is apt to throw it out, and leave a vacant place which degenerates into a hole, and the light becomes diminished. Three methods of coring will be explained, with diagram of coring machine, in my next article.

(To be continued.)

ON AN ACCIDENTAL ILLUSTRATION OF THE EFFECTIVE OHMIC RESISTANCE TO A TRANSIENT ELECTRIC CURRENT THROUGH AN IRON BAR.*

BY SIR WILLIAM THOMSON.

The wonderful accidental experiment of Lord Armstrong, to which attention was directed in *The Electrician* for March 21, 1890, may be briefly described as follows:—A bar of steel which Lord Armstrong was holding in his hand, was allowed accidentally to come in contact with the two poles of a dynamo giving 85 amperes and 103 volts. A painful sensation of burning was instantly felt, and the bar was dropped. Severe blisters occurred where the hand or fingers touched the bar, which was found immediately afterwards to be quite cold, or not perceptibly hot. This marvellous incident proved: (1) the outer surface of the steel to have been intensely heated; (2) that not enough heat was generated to sensibly warm the whole bar. The explanation, of course, is to be found in the known laws of diffusion of electric currents though non-magnetic conductors, considered in connection with the effect of magnetic susceptibility, of unknown amount and law, in conductors of steel and iron.

The requisites for working out fully the theory of transient or periodic currents in conductors of any form are included in Maxwell's fundamental equations, and are given explicitly for straight cylindric conductors of non-magnetic material in §§ 685-689 of his great work. Lord Rayleigh, in his Paper "On the Self-Induction and Resistance of Straight Conductors" (*Phil. Mag.*, May, 1886), gives the formula for transient or periodic currents in straight cylindric rods of iron, on the supposition of constant magnetic susceptibility. The details of this highly interesting and important branch of the subject have also been investigated by Heaviside in a very comprehensive manner. The tendency of periodically alternating currents to be condensed on the outer part of a cylindric conductor, while the current may be exceedingly feeble or quite insensible in the central parts, was discussed and explained by Lord Rayleigh in p. 388 of his article already referred to, and its aggravation in an iron conductor specially pointed out. The same considerations show that a transient current resulting from the application, for a very short time, of the electromotive force of a voltaic battery, or of electro-magnetic induction acting not directly on the cylindric conductor considered, but on a conductor such as the inductor of a dynamo of any kind, momentarily in circuit with it, is only skin-deep if the duration of the electromotive force be but short enough; and that the depth to which the current penetrates in a given very short time is much smaller for iron than for copper.

To find something towards a mathematical solution for the increasing current at any instant during the electric contact of Lord Armstrong's experiment, it is convenient first to consider the problem of finding the subsidence of current initially given in a circuit of two long parallel bars connected by end bridges, or in a circuit of one long bar insulated, within a conducting sheath, except at its ends, which are in metallic connection with the sheath. If afterwards we suppose the conductors and one end bridge to be given with no current, and that a voltaic battery giving constant potential be suddenly applied instead of the other end bridge, the rise of current through the parallel conductors from its initial zero to its ultimate steady amount will follow *nearly* the same law as the fall from the initial steady current to the final zero in our former simple case. The law will, indeed, be *exactly* the same if the quantity of positive electricity on one conductor, and of negative electricity on the other, requisite to charge them as a condenser in virtue of the gradient of potential, is nothing in comparison with the quantity flowing through the circuit. The quantities of electricity set in motion in consequence of electrostatic and of electro-magnetic induction vary considerably in relative importance, according to the problem considered. For many telegraphic and telephonic problems the static charges are by no means negligible, and in the ocean-cable problem they are of paramount importance, the electro-magnetic induction with which we are now occupied being in this case quite negligible. In shorter cables, and with high-speed action, both the electro-static and electro-magnetic induction must be taken into account, and both have been practically considered by Heaviside in the mathematical theory of the telephone. In the vast majority of laboratory arrangements, the currents required for the static charges are quite negligible, as is also the case with Lord Armstrong's experiment, so that the problem is reduced to considering the natural subsidence of a current under the action of no electromotive forces save those induced by its own rate of change.

In all cases of electric currents given in parallel straight lines, and left to subside, naturally the thermal analogy is most convenient. For electric conductivity, we have thermal capacity divided by 4π; for magnetic permeability, the reciprocal of thermal conductivity; and for current density, temperature multiplied by thermal capacity. Thus, if two infinitely long straight parallel conducting bars, separated by insulating material, be given with equal currents in opposite directions through them, and left to themselves, we have precisely the same mathematical problem to solve as if in every line of the thermal analogue we had initial temperature multiplied by thermal capacity given equal to the current density in the corresponding line of the electro-magnetic problem, and the system left to itself, with the positive and negative temperatures in the two bars subsiding towards zero. The quantity of heat generated per unit of area per unit of time, at any point of either interface in the thermal analogue, is equal to the rate of variation per unit of length along the electric conductor of the electrostatic force in the insulator in contact with it in the electric analogue. The fall of temperature in the latter case will correspond in some respects with the diminution of current in the former, and the rise of current in

* Abstract of Paper read before the Royal Society of Edinburgh, March 17, 1890.

Digitized by Google

different portions of the conductor when suddenly subjected to an applied electromotive force will correspond with the rise of temperature in different parts caused by the sudden exposure of the surface of the body to a high temperature.

Sir William Thomson then considers the case of a bar of circular section surrounded coaxially by a hollow circular cylinder. To further simplify matters he further supposes that the conductivity of the sheath is very great. The problem then becomes mathematically the same as that of a heated cylinder allowed to cool, which was presented and fully solved by Fourier in the sixth chapter of his "Théorie Analytique de la Chaleur." The numerical values to be taken in representation of the various physical properties of the material are then considered. Thus the permeability of the steel is taken as 300 by way of example and illustration; but as the permeability varies enormously with the amount of the magnetising force, and in a manner desperately complicated by hysteresis, no accurate mathematical investigation is practicable with only our present knowledge to guide us. The conclusion arrived at in this particular case is that during the first $\frac{1}{4000}$ of a second, the diffusion is unaffected by the curvature of the conductor, and follows sensibly the law of plane laminar diffusion. The supposition of the circular cylindric sheath of negligible resistance, adopted for the sake of simplicity, may accordingly be departed from, since the solution will be nearly the same for the case of two parallel rods, provided the distance between them is a considerable multiple of the diameter of either. Although the circumstances in Lord Armstrong's experiment are of such extreme complexity that it is of no use to attempt to work out a complete mathematical theory, it seems probable that the solution thus indicated and represented by Sir William Thomson's diffusion diagram* fairly illustrates the circumstances of the current which actually flowed through the steel bar. At all events, ample explanation of the intensity and suddenness of the effect perceived by Lord Armstrong is obtained by working out the result numerically of what would take place if a difference of potentials of 100 volts were suddenly instituted and forcedly maintained constant during one, two, or three ten-thousandths of a second between the ends of the bar.

It must not, however, be supposed that the difference of potential between the ends of the bar was in reality constant at 100 volts, even for so short a time as this. What was really constant was the strength of current through the electrodes leading from the complex dynamo circuit of armature, and shunt and series coils of the electromagnet, to the external lighting circuit, and to the temporary circuit through the steel bar. The immense quasi-inertia of each partial circuit within the dynamo prevented any great augmentation of the outgoing current during the few hundredths of a second during which the short-circuit occurred, and, with probably no practical error, it may be supposed that the outgoing current was constant at 85 amperes, the electric lighting circuit losing as much current as that which was passing through the bar. Since the quasi-inertia of the lighting circuit was very small, it seems quite probable that the whole of this current for the first few thousandths of a second passed through the outer skin of the steel bar. There is thus no difficulty in understanding the origin of the sudden high temperature of the surface which Lord Armstrong perceived, and yet that the whole amount of heat generated was insufficient to heat the bar to any sensible degree. If the dynamo had been doing no work externally at the time of the accident, the time required to get up a strong enough current out of the dynamo to produce much heating effect would have been very much longer than it was.

ON THE RESISTANCE OF HYDROGEN AND OTHER GASES TO THE CURRENT AND TO ELECTRICAL DISCHARGES, AND ON THE HEAT DEVELOPED IN THE SPARK.†

BY E. VILLARI.

An arc-light between carbon points of 1cm. diameter is well known to be shorter in a horizontal than in a vertical direction; and the arc is somewhat longer in a vertical position with an ascending current than with a descending one, doubtless owing to the greater heat of the anode, which must become more strongly heated when it is uppermost.

Arc-lights were formed in glass bulbs which were filled with dry gases. The carbon electrodes were superimposed in a vertical position, and were then drawn apart from each other until the arc-light disappeared.

The arc was found to be far shorter in hydrogen than in carbonic acid, and in the latter, again, shorter than in air; the ratio of the lengths was about 3·9 : 7·4 : 8·5. In nitrogen, with an ascending current, it is about seven times as long as in hydrogen, and with a descending current it is 25·7 times as long. With decrease of pressure the arc lengthens in nitrogen, hydrogen, and coal-gas; in the two latter, however, it never attains the same length as that of the arc in air. With platinum electrodes the lengths of the arcs in carbonic acid, nitrogen, coal-gas, and hydrogen at ordinary pressures were in about the ratio 16 : 19 : 4·6 : 2·8.

The production of heat at the electrodes was determined for various gases with sparks from a Ruhmkorff's inductorium. The electrodes were thermo-elements of iron and German silver. The heating was investigated in two globes filled with various gases, in which the distance between the electrodes was almost identical. The heating of the negative electrode was greater than with the positive; the difference of the heating effect seemed also to be greater in nitrogen than in hydrogen.

A globe filled with hydrogen or with nitrogen was next used, through which the induction-spark was passed, and the strength of the current measured by a well-insulated galvanometer. The induced discharge was more enfeebled by a layer of hydrogen than by an equally thick one of nitrogen. Moreover, equally thick layers of hydrogen and nitrogen enfeebled the discharge as much as columns of water of 99 and 59mm. respectively. In order to diminish the induction-current by the same amount, the length of the spark in hydrogen was 33mm., in nitrogen 48mm., and in carbonic acid greater than 49mm. Hence the resistances were in the order—carbonic acid, nitrogen, hydrogen. The heating of the electrodes increases with the rarefaction.

The spark was then made to pass over the bulb of a mercurial thermometer in various gases. The temperature increased more strongly in nitrogen than in hydrogen both for the induction-spark and for the spark from the battery discharge. The heating with both was much smaller in hydrogen than in nitrogen, so that in passing through hydrogen the discharge has a much smaller electromagnetic and thermal intensity than in passing through nitrogen. By substituting for the spark other resistances the same result was obtained. A layer of nitrogen 47·6mm. in length enfeebles the intensity of the induced current to the same extent as a layer of hydrogen 36·95mm. in length; and a layer of carbonic acid 49mm. in length as much as a spark 33mm. in length with the battery discharge. The negative electrode is almost as strongly heated with the discharge in hydrogen as in nitrogen. With the discharge of the condenser it is more heated in nitrogen.

The spark was finally produced in glass tubes which were surrounded by small calorimeters filled with oil of turpentine. Under similar conditions the spark in hydrogen developed more heat than in nitrogen, which is just the opposite to what occurs in the measurement of temperatures. The same holds also for the discharge of cascade batteries.

THE DEVELOPMENT OF ELECTRIC TRACTION.

A perusal of some of the more recent American Papers dealing with the subject of electric traction cannot fail to cause English readers to reflect on the unsatisfactory rate of British progress in this direction when compared with the very rapid development on the other side of the Atlantic. The electric railway, although of European birth, seems to have emigrated. Whist in England there are scarcely twenty miles of road operated by electricity, in America we are informed, on Mr. SPRAGUE'S authority, that 1,500 miles are actually constructed or under contract. In this country there are only about ten electric railways to boast of, while in the States there are no less than 130 towns possessing one or more such roads; and these require for their operation 1,700 motor cars and 3,000 motors, with an aggregate capacity of 45,000 horse-power. This remarkable development has, moreover, taken place within the last two or three years; for in 1885 the Americans were no further advanced than ourselves, and possessed no more than three railways, whose aggregate length did not amount to as much as eight miles.

The comparatively slow advance in this country certainly cannot be attributed in any degree to lack of skill among our own electrical engineers. The causes of it are the same as those which have

Digitized by Google

retarded the development of other applications of the electric motor, and are to be sought in the cheapness of coal and in the absence of water-power. Wherever natural sources of power are available, the transmission and distribution of energy by electricity has followed as a matter of course, and the familiarity with electric motors thus brought about has not only been of direct service in increasing the experience of engineers, but also, by familiarising the public with their use, has led them to expect further successful applications. The great difficulty in England has, indeed, been to induce an over-cautious public to believe in their commercial success; and this difficulty would be to a great extent removed if the actual working powers of existing motors were more generally known. It is not an insignificant matter that the two longest electric railways in the United Kingdom, namely, the Portrush Railway, on the SIEMENS' system, and the Bessbrook and Newry line, on the HOPKINSON third-rail system, are each worked by energy obtained from natural water-power, and to the success of the latter may be mainly attributed the fact that the City and Southwark Subway line is to be worked electrically. These instances are, however, quite exceptional. The cheapness of coal, the absence of water power, and the high state of development of other competing industries have, in this country, rendered profitable applications of motors hard to find; and the attention of electrical engineers has been so much concentrated on the commercial development of the dynamo for purposes of electric lighting that the possibilities in store for the electric motor have been somewhat neglected. It is true that motors have been applied with great success in mining operations, where in some cases the electrical plant has been found to be four times as efficient as the previous hauling plant, and several other important and successful uses for motors exist. The general result, nevertheless, has been that, although we have succeeded in manufacturing dynamos quite as good if not better than can be obtained elsewhere, we have nothing in motor development which can in any way compare with that which has taken place in America, where it is asserted that no less than 15,000 motors are at work in connection with as many as 200 different industries.

Returning to the subject of electric traction, it may be some slight consolation for us to remember that, although we can claim to have very few electric railways, every system in use is exemplified in one or other of them, and they are nearly all commercially successful. The Blackpool tramway, worked on the HOLROYD-SMITH system, is one of the comparatively few examples of the practical success of the use of conduits for tractive purposes; and its prosperity should give rise in this country to further development on the same lines. We have also at Barking an example of the use of accumulators for tramway purposes. Hitherto, although we have had numerous collections of statistics to display the advantages of battery traction, the various attempts to prove the practical truth of the statements made cannot be said to have passed much beyond the experimental stage. The future of battery traction is, however, by no means without promise; and when as much attention has been given to accumulators for traction purposes as for electric lighting, horse traction will have to encounter a formidable rival. It is, however, very significant, that while in England we have been content to experiment with single cars drawn along short lines, the Americans have reached the stage, not only of working suburban tramways electrically, but of seriously discussing the possibility of electrically driving express trains along the main lines. As far as mere discussion goes, we can claim to have developed the subject as much, if not more, than the Americans, since the advantages of electrically-driven railways formed the subject of a great deal of thought some years since, and many valuable patents have been granted from time to time to English inventors in this connection, as, indeed, reference to some of our recent issues will show. English development has, however, to a great extent stopped at the Patent Office. The much-talked-of proposal to drive some of the trains on the Metropolitan Railway by electricity has resulted in nothing; and the chief instance we can put forward to show that electric traction is making any headway in this country has reference to the City and Southwark Subway.

In America, however, development has taken place with extraordinary rapidity, and sanguine speculations as to the future of electric locomotion have recently been put forward across the Atlantic by men whose great experience of electric motors is universally acknowledged. Mr. SPRAGUE shows that the amount of copper needed for an electric railway between New York and Philadelphia is comparable with the amount of wire actually in use between Boston and New York for merely telephonic purposes, so that the cost of such a railway need not be unreasonably high on account of conductors. By dividing such a line into sections, with a stationary generating plant attached to each, Mr. SPRAGUE considers it well within the range of possibilities to bring about a 60-mile-per-hour express service of short trains every ten minutes in place of a 40-mile service every hour. Such a change would, as he says, revolutionise travel; and the greater comfort and cleanliness thus introduced, although looked upon as merely sentimental advantages until the new system is shown to be practical, would be acknowledged to be of great importance afterwards. The subject is again referred to by Dr. LOUIS BELL in a Paper on electric motors, which we reproduce in another column. Dr. BELL commences by referring to some valuable American Papers, wherein are recorded data obtained from actual experience with numerous street railways worked electrically, and, after a very practical discussion, he arrives at the conclusion that the diminution of efficiency arising from replacing the locomotive engine by the complex system of dynamo, conductor, and motor will be quite counterbalanced by the possibility of using stationary compound condensing engines of higher mechanical efficiency. An important point referred to is the fact that most of the loss in the electrical system arises from the double system of transformation of dynamo and motor, and not in the line itself; so that if, when the electrical efficiency is 50 per cent., the amount of copper is doubled, the efficiency would be only increased to 60 per cent. The many advantages of electric traction are discussed with especial reference to the working of overhead or underground lines in towns; and the author concludes with stating his firm conviction "that most of us will live to see electricity come into extensive use in general railway work, certainly for special and suburban roads, possibly for long through lines."

OBITUARY.

JOHN GEORGE DUNN.

The following extract from the *Chinese Times* of February 1st gives an interesting account of the labours of the late Mr. J. G. Dunn. To us he was known in 1871 and 1872 as private secretary to Sir John Pender, and he was also well known in the submarine telegraph world, where he had many friends. His unfailing good nature, his wide knowledge, and special aptitude in shipping matters stood him in good stead throughout his life. Although the following obituary notice only speaks of his career in China, Mr. Dunn was well known in London, St. Petersburg, and in Rome; and it is fitting that we should republish this commentary, giving, as it does, the main and closing portion of his not uneventful life. There are but few electricians and naval architects of standing who do not remember Mr. Dunn, and it

Digitized by Google

will be satisfactory to them to know that in his closing days in London he was carefully tended by the officers of the Eastern Extension Company:—

"Endowed by nature with extraordinary nervous energy, brilliant intellectual powers, and a daring spirit, Mr. Dunn exercised his faculties with unceasing diligence, accumulating vast stores of the most varied knowledge which a retentive and accurate memory rendered always available for use, so that he was a kind of walking encyclopædia. And being possessed by, rather than possessing, a special quality of wide-ranging patriotism which seemed to lay hold of all matters of national or international interest with as keen a grasp as if they were intimate personal concerns, he was entirely predisposed to busy himself in public affairs. His strong character gave a tone to his doings which lifted them far above the commonplace, for his standard of honour was high, his devotion to duty passionate and pure, and his fearlessness was that of those whose record can brook the fiercest light. His readiness to sacrifice himself at the call of duty was exhibited even to excess, and to that, indeed, he owed the illness which has carried him to the grave. A night and a day among the ice in an open boat on Taku Bar, with the thermometer below zero, followed by a cart journey to Shanghai in the severe weather of January, 1887, broke up a constitution already worn by painful maladies, and during these three last years the brave heart may be said to have been at hand-grips with death.

Mr. Dunn was best known, perhaps, in connection with ocean telegraphy, of which he was the true pioneer in China. The line which is owned by the Great Northern Telegraph Company was entirely of his conception, and by his sheer energy he carried his scheme so far that he obtained for his somewhat languid backers the actual concession from the Russian Government, which was snatched from him by Court influence and given to the Danes, who acknowledged tardily the wrong that had been done. The first semblance of an agreement with the Chinese Government for the landing of a cable was effected by Mr. Dunn on behalf of the Eastern Extension Company; and any one who is acquainted with the deadness of British representation in China in those days will understand that the dynamic force required to impel it to the needful activity was of no ordinary character. As often happens to leaders of ardent temperament, and as happened to Mr. Dunn on several occasions, he found himself in advance of his supports, obtaining privileges of value which his principals were either too slow to appreciate or were unprepared to take advantage of. The quasi-concession to the English Telegraph Company was allowed to sleep, the Great Northern Company assumed the privilege of laying the cable between Hong Kong and Shanghai, and Mr. Dunn saw himself once more supplanted by the same company which had ousted him at St. Petersburg years before, a disservice which did not slip his tenacious memory.

In process of time the Great Northern Company succeeded in negotiating with the Viceroy Li the concession of a monopoly of laying cables on the Chinese coast, which, if carried into effect, would have entirely superseded the agreement previously made with the English Company. The concession, which was vicious in itself, has remained inoperative, owing very much to the vigorous action in various directions taken by Mr. Dunn, who eventually compelled the Danish to seek an alliance with the English Company; and in concert they effected—but not without enormous difficulties, which were overcome by the *savoir faire* and indefatigable perseverance of Mr. Dunn—amicable arrangements with the Chinese Provincial Governments for the landing of cables and connection with land-lines on the coast, notably at Foochow and Canton. The ultimate agreement for working the various systems of telegraphs, viz., the English and Danish ocean lines and the Russian and Chinese land lines, remains to be settled; but that there is a practicable basis of agreement at all is due mainly to the untiring zeal of Mr. Dunn.

In the politial sphere Mr. Dunn's activity was necessarily more obscure, but its influence was by no means inconsiderable, as he had by his sympathetic manners and really vast information the faculty of gaining the confidence of most of the important individuals with whom he was thrown into contact. In this way he ingratiated himself with the Japanese Minister Iwakura, who drew on Mr. Dunn's exhaustless stores for the knowledge which was so much needed in the construction of the New Japan, on matters political, international, naval, military, and educational. During the crisis of 1874, when Japan had invaded Formosa, Mr. Dunn was made the bearer of messages between the two countries which formed the basis of the solution of the differences effected through the official intervention of the British Minister in Peking. Nor was that the only occasion in which his peculiar abilities were made use of in questions bearing on the relations between China and Japan.

Among Mr. Dunn's many accomplishments his mastery of naval and military science was probably unique for an amateur, and he had the faculty of rapidly assimilating all the current information on these subjects, wherever published. Nothing escaped his keen eye, and he was always posted up on the latest inventions. Nor was his learning superficial, for we have known experts of the highest standing avail themselves of his aid in difficult questions of naval construction, while competent military critics have confessed that his schemes for the establishment, armament, transport, and mobilisation of an army for China were admirably suited to the circumstances of the country, and in advance of rather than behind the times when they were compiled. Mr. Dunn's adroitness and capacity for collecting intelligence on these matters enabled him to render valuable service to his own Government on several occasions when it was important that they should be accurately informed concerning the defensive positions of China and Japan; and to the British Legations in both countries he was at different times a volunteer naval and military attaché, seeking no acknowledgment of his services. Probably this is the first time his name has been mentioned in connection with certain valuable reports which enrich the archives of the two legations. The Papers on defensive organisation which he has supplied to the Chinese Government would furnish the bureau of a Ministry of War.

One of the most important missions with which Mr. Dunn was charged was that from China to the Vatican, in 1886, of which the time has not yet come to give a full account. It was a mission which called for the finest diplomatic tact, and Mr. Dunn's qualifications for the task were special and unique. In its inception the Chinese Government, or, to speak quite correctly, the Empress-Dowager, had one object in view, which they had tried by various means to attain, without success,—the removal of the Pei-t'ang Cathedral from the precincts of the Imperial palace, for which the assent of the Pope had to be obtained. In receiving his instructions, which were conveyed through the Viceroy Li, Mr. Dunn, with the ready resource which seldom failed him in emergencies, saw the opportunity of tacking on another question vastly more important for China than the expropriation of the cathedral, viz., the diplomatic representation of the Holy See in Peking. An invitation for a papal legate was embodied in Mr. Dunn's instructions; but it seems probable that the Chinese themselves never fully comprehended the import of that question, and, while they were looking only for the removal of the cathedral, were amazed at the commotion which was set up in Europe by the mooting of the Christian protectorate which was involved in the nomination of a legate, and which agitated the French Republic to its foundations. No question, indeed, during the present generation has so strained the relations between France and the Vatican; and in defence of her phantom of a protectorate over Chinese Christians the Republic had prompt recourse to her *ultima ratio*, under which the Holy See was compelled for the time to lower its colours."

REVIEWS.

A Treatise on Statics with Applications to Physics. By G. M. Minchin, M.A. Vol. II. Fourth Edition. 1889. (Clarendon Press.)

When the first edition of this work, in one small volume, made its appearance about a dozen years ago, its advent was hailed with delight by teachers and students alike. The reason for this is not far to seek; for, appealing to students with a sound and moderately advanced knowledge of pure mathematics, but who had not attained the heights necessary to enable them to cope with the profound, and, we may add, profoundly difficult, work of Thomson and Tait, it provided them for the first time with an exposition of the subject of statics, or the equilibrium of forces, considered from the physical point of view, and not as a series of exercises in pure mathematics. The author followed from the first the excellent example set by Thomson and Tait in utterly eschewing the consideration of ingenious mathematical problems based upon hypotheses which had no experimental foundation, but had been devised for the most part in order to provide tests of the mathematical ingenuity of candidates at Cambridge examinations. Another very valuable feature, and a novel one in English text-books, was the free use of the graphical methods which are of such fundamental importance to the modern scientific engineer, and which, moreover, are of pre-eminent value in awakening the intelligent interest of the student.

The subject of electrostatics, which does not usually find a place in treatises on statics, had, with great advantage, a short chapter devoted to it in the first edition. In the second and subsequent editions this feature was further developed, and

Digitized by Google

supplemented by the introduction of the subject of stresses and strains, treated in a manner which made this portion of the greatest value to students of electricity, magnetism, or physical optics. The work has now expanded into two octavo volumes, of which the first treats of forces in a plane. The second volume, which is considerably the larger of the two, treats of non-copianar forces, astatic equilibrium, the principle of virtual work applied to any system of bodies, the equilibrium of strings and springs, the theory of attraction, including the theory of potential, and an introduction to spherical harmonics, stresses and strains, and electrostatics.

In the chapter on astatic equilibrium the vector method is employed, which greatly simplifies the treatment. This chapter contains a very clear and simple discussion of the astatic equilibrium of a heavy magnetic body, and a simple construc tion is obtained for the determination of the astatic centre, or point at which a single force will keep the body in astatic equilibrium for displacements in the plane of the magnetic meridian. The chapter on the principle of virtual work contains some valuable observations on Langrange's method of applying the equation of virtual work to continuous material systems, pointing out that in his treatment of certain cases he makes an assumption which is not always justified, and in some instances has led him into error, and may possibly mislead others in applying the method.

The attention of the electrical student should be called to the exposition of the theory of potential, which is brief, but very clear. It includes a discussion of magnetic shells.

The chapter on attraction concludes with an admirable section on Green's theorem, which the author, with justice, characterises as probably the most remarkable and powerful analytical result in the whole range of mathematical physics, and on spherical harmonics, which play so important a part in the mathematical treatment of electrical problems. The exposition of the elements of spherical harmonics is brief, but very clearly put, and the student will be greatly assisted in mastering it by the numerous fully-worked-out examples by which it is followed. This plan of giving a full discussion of carefully selected examples is carried out throughout the work, and is one of its most admirable and helpful features. These worked-out examples are supplemented by many others, which are left for the student to solve for himself.

The chapter on stresses and strains will be found of great assistance in understanding Maxwell's chapter on the mechanical action of two electrical systems. Perhaps the most interesting portion of this chapter on stresses and strains is the section on the "propagation of gravitation," in which the author discusses the celebrated theory given by Maxwell in the chapter referred to, according to which all actions excited between two material systems, according to the law of the inverse square of the distance, can be produced by a distribution of stress over closed surfaces in the medium in which they are immersed.

The chapter on electrostatics, like the rest of the book, is extremely good, and the student will find it of great assistance as an introduction to the study of Maxwell's treatment of the subject.

"L'Année Électrique." By PH. DELAHAYE. Sixth year. (Paris: Baudry et Cie.)

This is a handy little work, in which will be found a brief reference to the most important electrical events and inventions of the past year. It is divided into eleven chapters, dealing respectively with electric lighting, batteries, telegraphy, telephony, atmospheric electricity, medical electricity, electrolysis and electro-metallurgy, electricity applied to railways, electrical distribution and transmission of energy, measuring instruments, and obituary. The volume is, on the whole, well up to date and complete. In Chapter I. we have a description of the Kapp regulating transformer, and in Chapter III. several pages are devoted to Messrs. Wright and Moore's printing telegraph and to Mr. Langdon Davies' phonopore. Tolerably full notices are also to be found of the Webster sewage and the Hermite bleaching processes; of the Leblanc alternate-current motor, Hookham and Shallenberger meters; and to Mr. Shelford Bidwell's interesting researches on the effect of light on the magnetisation of iron.

Almanach-Annuaire de l'Électricité et de l'Electrochimie. Année 1890. (Paris: Firmin Leclerc.)

This is the sixth year of the publication of this useful guide to the electrical trades in France, Belgium, and Switzerland; and, like other Electrical Directories, it bears witness to the continued growth of the industry. The Annuaire is divided into five parts. Part I. contains lists of the members of the chief French electrical societies. Part II. is a directory to the various electrical industries in Paris, which are grouped under about 180 different headings. Part III. is a guide to the electrical industry outside Paris, each department having its separate list. Parts IV. and V. deal with Belgium and Switzerland. The volume seems very complete so far as it relates to Paris, to which nearly 120 pages are devoted; but the information with regard to the whole of the rest of France is contained in one-third of this space. A general alphabetical list of names would be a decided addition to the Annuaire.

ON ELECTRIC MOTORS IN GENERAL RAILWAY WORK.*

BY DR. LOUIS BELL.

The title of this Paper makes it sufficiently evident that I do not intend to indulge in retrospection, except in so far as is necessary for illustration, but shall turn my attention to what is now a probability of the future. The electric motor for street-car service is an accomplished fact, as some hundreds of miles of road in daily operation bear witness. So far as practical success is concerned, the electric railroad is past the experimental stage, and is in the beginning of the commercial era. Many improvements will be made in the future, as they have been in the past, and the direction which some of the improvements have taken suggest and emphasise the probabilities I am going to discuss to-night.

First we must notice that in a large measure the running of single cars has been abandoned except on small roads and heavy grades. A good proportion of electric railroads now regularly use trailers attached to their motor cars, and sometimes trains of two or more. To meet this demand for trains rather than single cars a heavier type of motor has been introduced, and even heavier ones are being projected. A powerful motor car with a couple of trailers attached cannot fail to suggest to the mind a possibility of a still more powerful car at the head of a procession of a couple of baggage cars, two or three day coaches, and as many more sleepers. Enough experiments have already been tried to show that motors nearly or quite as powerful as an ordinary locomotive can be readily made and handled.

Besides knowing the general properties of our present electric railroad, we are now in a position to make a fairly good estimate of its operating expenses. The best discussion of this which has yet appeared is the recent Paper by Mr. O. T. Crosby (*The Electrician*, January 3rd, 1890). His results are worth the careful study of any one interested in the particular subject now before us; and while some of his data were necessarily imperfect, they give a very good general idea of the facts.

Some recent changes in street railway practice may prove suggestive in this connection. First, we must notice the growing use of large and powerful compound-wound generators. An ordinary shunt-wound machine is ill suited to railway service, on account of the very great variations in load, and consequently in voltage; nothing short of compound-winding can or does keep the voltage reasonably constant, and the change is a most decided improvement. Besides this, the voltage in general use has been constantly rising. Less than two years ago, a well-known electrician said that he did not favour the use of more than 400 volts for railway work; there are now many roads on which from 525 to 550 volts at the station is the rule, and pressures as low as 400 volts at the station are quite the exception. This increase in voltage is probably a distinct advantage. In the early days of electric railroading, a couple of years ago, the art of insulating armature and field coils was by no means as highly developed as it is now, and I think we shall soon reach the point where the voltage used for railway work will only be limited by considerations of public safety, and only, therefore, when overhead circuits of bare wire are used. It is gratifying to learn that at the Kansas City Convention it was agreed to adopt, as far as possible, a uniform standard of 500 volts for railway work. We are quite certain now that 500 volts cannot be classified as a dangerous potential—at least, if the current is a continuous one; how much higher than this the limit of safety lies we do not know, though it is quite certainly below 1,000 volts. In-

* Read before the Chicago Electric Club, March 17, 1890.

Digitized by Google

creased voltage means increased efficiency in distribution, and increased efficiency of motors if we can secure the necessary insulation. If we are ever to use powerful motors at a long distance from the generating station, the necessity of high voltage is apparent. The possibility of using high voltages need not be questioned, for in the experiments of Deprez and the more recent experiments at Kriegsteten, potentials from 2,000 to 6,000 volts were quite successfully used. The necessity for high voltage may compel us to use Gramme armatures to secure insulation, but there is no serious obstacle.

Another recent important improvement in motor work is the very general use of carbon brushes, which has facilitated the operation of railway motors in a most remarkable manner.

In looking at the possibility of handling large trains with motors, two questions naturally arise before we can even consider the advisability of attempting it. First, can we readily build a motor to handle railroad trains at railroad speeds? To this question I think we can unhesitatingly answer yes. The experiments of Mr. Daft on the New York elevated road make it very clear that we can build motors large enough to do the work with every hope of success. In those experiments trains of the ordinary weight for elevated work were handled at a speed higher than that required by schedule time. Aside from this, stationary motors of equivalent size are already in use in mining operations. In fact, with large motors, say from 50 to 150 horse-power, we should expect to obtain rather greater efficiency than in the sizes more generally used.

We should expect, theoretically, to obtain a rather higher weight-efficiency with the larger machines. In practice very many manufacturers do not increase the weight-efficiency with the size of the machine. The reason for this I do not know; possibly because a machine of lower weight-efficiency is sometimes cheaper to build. This question aside, there are certain advantages of a practical nature in using these large motors. When a motor becomes too large to be put under an ordinary car body, and a special motor car is constructed to hold it, it works under conditions very much more favourable to smooth and successful running, for it is far less exposed to accident and the continual small troubles arising from dirt than an ordinary street car motor. Then, too, it is possible, not being cramped for space, to arrange the whole motor outfit in such a way that it can be given close and careful attention.

The second question before-mentioned is, can we rely on a motor with anywhere near the same feeling of certainty as on a locomotive? A couple of years ago we should have been compelled to answer this question in the negative, but the great and rapid improvements that have been made in insulation and the various details of construction make one hesitate in giving that answer. We must remember that dynamos of corresponding size are in daily use, and frequently run months, many hours a day, without the necessity of shutting down for any purpose whatever. Given a powerful motor, placed in a motor car where it can have as close attention and as watchful care as any dynamo in a central station receives, and I know of no reason why it should be subject to break-downs or require frequent repairs. To be sure, a motor is subjected to sudden and violent changes of load, but if well made to begin with, and taken good care of, I do not think we should have good reason to fear its being unreliable. The case is not at all comparable with that of ordinary street-car motors, which, besides lacking even a reasonable amount of care, are subject to dirt and dampness to a degree that makes it wonderful that they do not break down oftener. A motor placed in a special motor car, and properly protected, ought to run as successfully as a stationary motor, and thus, unless grossly overloaded, give singularly little trouble.

Putting aside, then, these questions, as those that can be reasonably answered in the affirmative, we come to another vital question: Can the requisite amount of power be transmitted with a tolerable degree of economy to the distances required? This question we are now in a position to answer. It is apparent, I think, at first sight that we cannot expect to distribute over very long distances without a frightful sacrifice of economy. The electromotive forces used are somewhat limited by the possibilities of insulation, and economy of long-distance transmission can only be secured by very high electromotive forces or an enormous expenditure of copper. The immediate solution of this difficulty is to operate the line in sections of reasonable length, and this, of course, can easily be done. This at once raises the question, what is reasonable length? And to answer this question we should have to investigate each special case in detail, for the most economical length of section would involve the relation between the loss of power in transmission over a long distance, and the increased expense of shortened sections, a ratio which evidently involves too many variables to admit of a general valuation.

A question that naturally comes up in this connection is, whether it might not be possible to obtain the best results by means of a constant-current motor and generator? The mechanical difficulties of keeping a long line in order for real series transmission are, I think, too formidable to make this aspect of the question worth discussing, until they shall have been effectively disposed of for short-distance work. If we were only operating, however, one motor per section of line—in other words, transforming the system into a real block system—I am not at all sure but that the constant-current motor could be very successfully used, although its application to railroad work is as yet new. A curious complication is introduced by the fact that if we were to operate a long line of sections, we should find, as the inspection of any time-table will show, that on certain sections no more than one train would be running at one time, while on others several trains would have to be operated simultaneously. On these last sections, larger distributing conductors would be needed, and a little study of the time-table might result in a very considerable saving of copper. As the motor used would be a series motor in any case, I see no objection to working it at a constant-current on one-train sections, if anything were to be saved by it.

I will now consider the power which might be required and the economy that might be obtained in an actual case, taking a single section for an illustration:—

The case which I am going to suppose is a transformation of the Big Four line from Chicago to Cincinnati into an electric road, so far as passenger trains are concerned. The length of the line is a trifle over three hundred miles, and I shall suppose it to be divided into some ten or twelve sections, each with a power station at its middle point. This arrangement of the power stations evidently will secure the greatest average economy. The road is a single-track one, and the hypothetical section which I shall investigate is the section between Kankakee and Sheldon, Indiana, a distance of thirty miles. I take a case of this sort to show what will be the actual power required and the proximate economy in case of an actual railroad running its regular trains on its present schedule time. In looking over any time-table, it will be noticed that any such given section will only require power at certain hours of the day, and a varying amount, according as one or more trains may be operated at the same time. Having worked out the times for supplying power, and the probable amount, I shall then investigate the probable economy of an hypothetical electrical equipment. Looking over the time-table of the Big Four line, between Kankakee and Sheldon, it appears that by changing the time of two local trains from Kankakee to Sheldon, which do not connect with anything, and by changing that time only a few minutes, it would never be necessary to operate more than one train on the section at a time. Making these changes, the hours of supplying power would be 10:25 a.m. to 3:10 p.m., 10:25 to 11:32 p.m., 3:20 to 4:30 a.m. The problem then resolves itself into supplying power enough to operate an ordinary train at the usual speed, and at a maximum distance of 15 miles from the power station.

Let us now suppose the motor to work at 1,500 volts at its terminals at the end of the section. The power required to operate the train would be about 200-250 horse-power at the average speed, consequently the current transmitted over the line would be 100-125 amperes. Of course we might suppose any number of hypothetical line equipments, but I shall confine myself to one in which the amount of copper required will not be specially forbidding. I shall suppose a line wire No. 0, connected at short intervals to a bare trolley wire of silicon bronze or some similar alloy. The conductivity of this system is more than equivalent to a single wire No. 000, on which I should base my calculations. I should suppose track and ground systems to be made in the ordinary way. The length of conductor on each side of the central station would be about 79,000ft., and the fall of potential for 100 amperes over this distance would be a little over 500 volts; the generator, therefore, would have to develop a little over 2,000 volts, and the line efficiency at the terminals of the section would probably be somewhere near 75 per cent. The average line efficiency for the entire section would probably be somewhere near 85 per cent. The total amount of copper required for the section would be about 110,000lb. including insulation, or about 3,600lb. of copper per mile. With, therefore, this amount of copper, which seems not at all excessive, we should have an average line efficiency of about 85 per cent. Now assume a commercial efficiency of the generator of 90 per cent., and assume for the efficiency of the motors and gears 80 per cent., which for motors running at high speed and with infrequent stops does not seem an excessive estimate; the mean commercial efficiency of the combination would be a little above 60 per cent. In other words, taking into account all sources of loss, we should probably have an efficiency of a little over 50 per cent. from the indicated horse-power at the engine to the power supplied at the axles of the car.

Now let us look a little further and see the amount of power which would have to be supplied to the section which we have been considering. Looking over the time-schedule, we see that power is required for almost exactly seven hours, and to supply the 200 horse-power necessary at the train we should have to furnish about 400 indicated horse-power at the power station. We should, therefore, furnish 2,800 horse-power hours to the section under consideration, and we should have the advantage of being able to use

Digitized by Google

compound condensing engines. These engines ought to be able to furnish the indicated horse-power hour on two pounds of coal; the coal required for our supposed section then would be 5,600 pounds for the 24 hours. Banking fires between runs would consume some little coal besides, but, with proper engines and good firing, the 2,800 horse-power hours ought to be furnished on three tons of coal.

We are now in a position to form a tolerably clear idea of the probable cost of equipping such a section as we have been discussing. We shall require for equipment a 400 horse-power compound condensing engine and dynamo to match, then we shall require, as before mentioned, a little less than two tons of copper per mile. In return for the investment in these items, we get an average commercial efficiency of a little over 50 per cent., and the question to be raised is the exceedingly practical one, Will it pay? We gain the advantages of being able to use a very economical engine and of being able to dispense with a certain number of employés. To make these gains we content ourselves with an efficiency of 50 per cent. It is worth noting, too, that the mean efficiency of such a section cannot be raised to a very high figure, for the reason that even with the small amount of copper specified, most of the loss is in the double transformation affected by dynamos and motors, and not in the line. If the amount of copper were doubled, we should still have to be content with a total commercial efficiency of about 60 per cent. In Mr. Sprague's very able Paper (*The Electrician*, March 7, 1890), read before the National Electric Light Association, he has pointed out the economy secured by multiplying power stations and using shorter sections. Without going into detailed estimate, it would seem doubtful whether there would be much practical economy in an extensive system of power stations. The three-wire system suggested by Mr. Sprague in the same Paper is a much more practical way of securing economy, and may come into extensive use. On a double-track road, such as we have in suburban or elevated roads, this three-wire system could be operated to very great advantage.

Let us now look at the locomotive a little for the purpose of seeing whether we are going to gain enough in saving coal and wages to pay for 40 or 50 per cent. energy lost in the various transformations of the electric system. There seems to be a widespread popular delusion to the effect that the locomotive is an exceedingly uneconomical machine. On the contrary, the figures of actual tests show that the locomotive compares very favourably with ordinary non-condensing engines of similar size. Figures obtained with the Strong locomotive show some of the runs as being made on less than four pounds of coal per indicated horse-power, and the average result being most remarkable. Various foreign experiments point in the same direction to show that a well-cared-for locomotive will give the horse-power-hour on 27 to 30 pounds of water. As it is now, then, the locomotive appears to be rather more economical than the average non-condensing single engine, but if the locomotive is ever pushed hard by any other motive power, it will be developed in the direction of compounding. We have already enough tests of compound locomotives to form a pretty distinct idea of the saving that can be effected, and, on the whole, we must conclude that, in the matter of efficiency, the compound locomotive gives about the same results as any other compound non-condensing engine.

It would appear, then, that the saving of fuel effected in the electric system would practically be that due to the difference between condensing and non-condensing engines. The saving in fuel would probably be about one-half. The saving in employés would be comparatively small, as two or three men would be required to operate each power station. The margin of economy, therefore, between an electric system and locomotives appears to be about enough to balance the losses in the transformation in the electric system. This latter, however, has two additional advantages that tend to economy. In the first place, a somewhat cheaper grade of coal can be used with a stationary engine, because better firing is possible. In the second place, an electric locomotive would have a decided advantage in the matter of weight-efficiency, which ensures a slight economy in power. I should say that an electric locomotive of the power we have been considering would weigh from 30 to 50 per cent. less than an ordinary locomotive with its tenders. One instinctively asks if this lighter weight does not mean decreased tractional power? And hence, does it not work to the disadvantage of the electric locomotive? This opens the question of the effect of using the rail return for the current which supplies the power. Most of those who have studied the subject think that the adhesion is somehow greatly increased by the passage of the current from the wheel to the rail. So far as I am aware, there are no experiments, under anything like working conditions, which give us a definite idea of the facts. That the general opinion is well founded I have little doubt, and in looking over some of my note-books I have found some experimental evidence. This was a fact well known, I presume, to others who have experimented on electric cars, that the ratio between the power required to start a car and that required to keep it in motion is quite out of proportion with the results one would expect, judging from dynamometer tests on ordinary street cars. I am of the opinion that the increase in adhesion, even under ordinary working conditions, is very considerable. Where very heavy currents are used, we know from actual experiment that such is the case, as has been shown by Mr. Ries.

And this naturally raises the question as to the possibility of reaching very high speeds by the use of the electric locomotive. Of course, in any case, increased speed means greatly increased power, and the question then becomes one of comparative weight-efficiency and adhesion. This comparison is certainly to the advantage of the electric motor; but we must remember that the limitations upon railway speeds to-day are not those set by mechanical difficulties, but by considerations of safety and economy, and these do not change in any marked degree with a change in the motive power. If it would pay to run railroad trains at an average speed of a mile a minute, it would have been done long ago, and there is no reason to expect that the use of electricity would quicken the running time, unless the public demanded it, and felt quite safe and reassured at the prospect of being hurled through space at the rate of a hundred miles per hour, or thereabouts. If there should be an imperative demand for very high speed, I think one may roughly estimate that the use of electricity would nearly double the speeds now in use; but the question of these very high speeds is purely a question of dollars and cents, for, as a rule, very fast trains are not found to pay particularly well. In the case of a suburban road, the saving in wages would be considerable, since one power station would suffice for the whole system; and the same, of course, is true of any large system operated from a single station.

(*To be continued.*)

THE PHYSICAL SOCIETY.

At the meeting of this Society on March 21st Mr. T. MATHER read a Paper—

"On the Shapes of Movable Coils used in Electrical Measuring Instruments."

In the Paper "On Galvanometers," by Messrs. Ayrton, Sumpner and Mather, read before the Society on January 17, 1890, it was pointed out that the coils of the d'Arsonval galvanometer should be long and narrow, and without an internal core. The author observed that the construction of the coil in Mr. Boys' radiomicrometer showed that he had previously arrived at the same conclusion. His object in the present Paper was to determine the best shape of the coil perpendicular to the axis of rotation. Though he had treated the question with reference to the d'Arsonval instrument, the reasoning would apply generally to other instruments with movable coils.

Suppose the axis of rotation of the coil to be perpendicular to the plane of the paper, and to intersect it at the point O (Fig. 1),

FIG. 1.

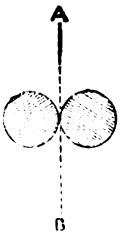

FIG. 2.

and suppose the direction of the magnetic field in which the coil moves to be defined by the line A B. Let P be an element of the section of the coil at a distance, r, from the axis, and θ the angle P O A. Then the deflecting moment excited by unit-length measured perpendicular to the plane of the paper is

$$H C a r \sin\theta,$$

where H is the strength of the field, C the current per unit-area of section, and a the area of the element. The moment of inertia of the element about the axis will be

$$W a r^2,$$

where W is the density, or mass of unit-volume, of the element. For ordinary commercial instruments the conditions to be fulfilled are a moderately short period and a minimum absorption of power. Therefore, since for a constant period the controlling moment at unit-angle must be proportional to the moment of inertia, the

Digitized by Google

problem is to determine the shape of the section so that the ratio of the deflecting moment to the moment of inertia may be a maximum. For the element considered this ratio varies as $\sin\theta / r$; since H, C and a may be considered as constants. Now it may be shown, as in Maxwell's "Electricity and Magnetism," Vol. II., p. 332, that a given length of wire will produce the maximum effect if wound within the surface of revolution formed by the rotation of the curve $p = x_1 \sin\theta$ about the axis, where x_1 is a constant. Thus this curve, which represents a circle tangential to A B at O, is the best form for the section, the complete form of which therefore consists of a pair of circles touching at O, as shewn in Fig. 2.

The section lines of the two circles are drawn in opposite directions to indicate the opposite directions of the currents in the two. The problem might also be treated by finding the shape and position of an area having a given moment of inertia about a point in its plane such that the moment of the area about a co-planar line though the point should be a maximum, viz., taking the point as pole, and the given line as the line of reference, the expression $\iint r^2 \sin\theta \, dr \, d\theta$ has to be made a maximum, subject to the condition $\iint r^3 \, dr \, d\theta = \text{constant}$. The question had previously been solved in this manner by Dr. Sumpner, to whom the author has suggested the problem.

The accompanying table illustrates the improvement obtainable by winding the coils in this manner.

—	Shape of Section.	Deflecting Moment / Moment of Inertia.	Deflecting Moment per unit moment of Inertia.
1		$\frac{4}{3b}$	1·02
2		$\frac{4\sin\theta}{3b\theta}$	·91 ($\theta = 30°$) ·95 ($\theta = 45°$)
3		$\frac{8}{3\pi b}$	·80
4		$\frac{4\sin\theta}{3\theta}\left(\frac{b_1^3 - b_2^3}{b_1^4 - b_2^4}\right)$	·44 $\left\{\begin{matrix}\theta = 19° \\ b_2 = \frac{12}{13} b_1\end{matrix}\right\}$ *
5		$\frac{3b}{2(b^2+a^2)}$	·97 ($2a = b$) ·91 ($4a = b$)
6		$\frac{3}{4b}$	·79
7		$\frac{3b}{t^2+a^2+3b^2}$	·47 $\left\{\begin{matrix}t = \frac{1}{15} b \\ a = \frac{1}{5} b\end{matrix}\right\}$ †
8		$\frac{b}{b^2 + \frac{c^2}{2}}$	·38 ‡ ·40 $\left(c = \frac{1}{11} b\right)$ §

* Low-resistance d'Arsonval. † High-resistance d'Arsonval.
‡ Ganz Wattmeter. § Siemens' Dynamometer (60 amperes).
|| Siemens' Dynamometer (500 amperes). ¶ Siemens' Wattmeter.

The numbers in the third column were obtained on the assumption that the coils were long in proportion to their breadth, a condition not often fulfilled; and when this was not the case the numbers would be still lower, since the parts of the coil at right angles to the axis of suspension add to the moment of inertia, but not to the deflecting moment. Taking this into account, a coil of section (1) would be about three times as efficient as one of sections (4), (7), (8), (9). The new coil would be heavier, and therefore require a stronger suspension, but owing to the considerable friction at the mercury cups, this would not seriously diminish the accuracy of the instrument.

The author then justified his assumption that the moment of inertia might be treated as constant by pointing out that whether the current were led into the coil by mercury cups, by wires which also serve as the control, or by flexible wires independent of the control, the control could not be reduced below a certain minimum, independent of the shape of the coil; and the period also being determined by considerations of convenience, the moment of inertia might be taken as constant. In case of a radial field, such as in the new d'Arsonval galvanometer, with a range of 180deg., the coil No. 1 would not be suitable, but one having the shape of No. 4 would be best. The shape No. 1 could not, of course, be imitated exactly in practice, owing to insulation space being required between the two halves, and in the Siemens dynamometer a considerable amount of space would have to be left for the mercury cups; but even in this case a much closer approximation to the best shape than the one ordinarily employed could be used.

DISCUSSION.

In the discussion which followed the reading of the Paper,

Mr. C. V. BOYS observed that although when the current had to be led into or out of the movable coils by means of mercury cups, it was often necessary to make them of shapes very different from that theoretically most advantageous, yet it was a great advantage in designing instruments to know the relative efficiencies of coils of various shapes. He himself had found while working at the radiomicrometer, that No. 1 was the most advantageous shape. He then pointed out that any coil could be transformed into another equivalent to it both dynamically and electrically by increasing or diminishing its length and section, and diminishing or increasing its width, all in the same ratio.

Prof. AYRTON observed that Prof. Perry and himself when first constructing the wattmeters had noticed the disadvantageous shape of the coils employed in the Siemens dynamometer, and had therefore adopted a different arrangement in designing their wattmeters.

THE MICHALES ELECTRIC MINING MACHINE.*

The accompanying cut shows the construction of a very simple and ingenious machine, constructed by the Michales Electric Mining Machine Company, of Pittsburg, Pa., and designed to adapt and utilise the electric current for the laborious portion of miners' work.

The machine is mounted on a two-wheeled truck. It is 9ft. in length, 1½ft. in breadth, 2¾ft. in height, and weighs about 850 pounds. It is supported with sliding axles for the purpose of balancing when a shorter or longer pick, R, is used. It is mounted with a 2 horse-power Tesla motor, A, from which the power is transmitted through a combination of gear wheels, B C E, and shafting, D, to a cam, F, rounding the drill bar, I. Within this cam F, on the drill bar I, is placed a thumb, b, on the end of which is a small trolley wheel to prevent friction as the cam F passes in front of it. By the rotation of this cam F, its inclined surface passes in front of this trolley wheel, forcing it back and up the incline F, drawing with it the drill-bar I, against the tension of a powerful spring K, which encircles it, until the vertical wall of the cam F passes beyond the trolley wheel, when it is automatically released and forced violently forward by the action of the spring K, the trolley wheel returning to the bottom of the incline F. In order to alleviate the shock to which the machine would be subjected in case the pick R should not strike against the coal, there is an extremely powerful spring N interposed between the shoulder M on the drill bar I and the front end of the tube L which surrounds it. The springs K and N, constructed especially for this machine, are of different tension and mathematically correct, and can be changed in a moment as the character of the work requires. The machine strikes 120 blows per minute and with a force of 9,000lb. to the blow.

The Tesla motor, manufactured by the Westinghouse Electric Company, has been adopted for operating the machine. This motor is peculiarly fitted for mine service, owing to its compactness in design and simplicity of construction. The unique and especially valuable feature is that the current in the armature is an induced current. The ends of the armature wires are soldered together, and there is no electrical connection between the armature and the outside circuits. There are no brushes to require adjustment, or to spark or burn out a commutator. The absence of commutator and brushes allows the armature, which is the only moving part of the motor, to be completely inclosed and protected from mechanical injury. No regulator of any kind is used, and the only piece of apparatus in connection with the motor is a simple switch. Owing

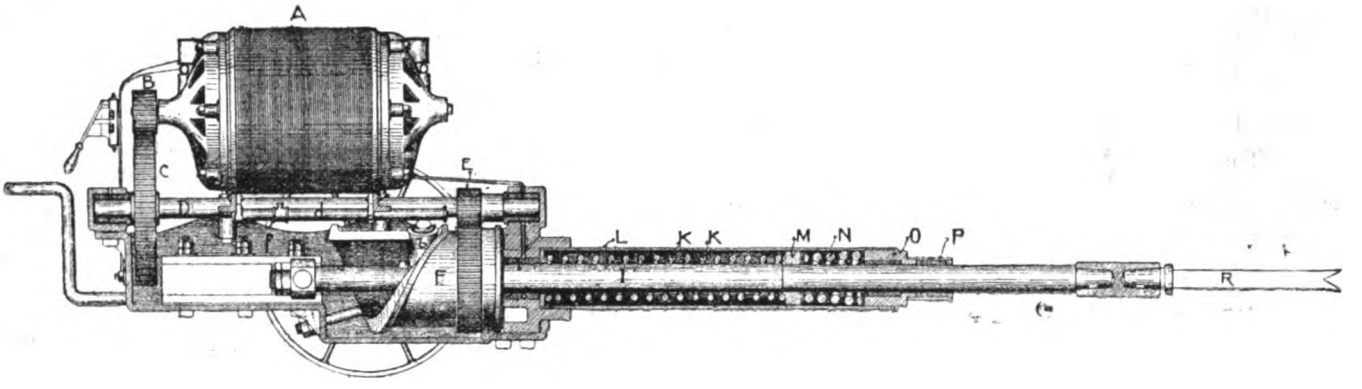
* From the *Electrical World*, March 29, 1890.

Digitized by Google

to the continuity of the circuit and the absence of brushes and bare contacts requiring adjustment or handling, it is perfectly feasible to use an electromotive force higher than could otherwise be conveniently handled. The motor has been operated with a pressure of 250 to 300 volts. It can easily be constructed for use with either a higher or lower pressure, according to the requirements in special cases. The extreme simplicity of the electrical part of this mining machine enables it to be put into the hands of miners who have had no previous experience with electrical machinery.

One very commendable and unique feature of this machine is that at whatever point in the stroke the pick is arrested, it is instantly returned from that point ready for the next blow; and when the blow is delivered, even though it be arrested in its course, instead of the machine pushing itself away from the coal, as one would naturally suppose it would do, it rather inclines to the coal, owing to the momentum of the drill bar. It will not interfere with the working of the machine where it is necessary to post close to the face of the coal.

The machine is light and easy to handle; being composed principally of steel, is very strong and durable, and will stand almost any amount of abuse. It is very simple, beautiful in design, and neatly finished. The method of operating this machine is as follows:—The machine having been placed to the coal, the operator takes his seat behind it, and having perfect control of it, places each blow, as would the hand miner, where it will be most effective, cutting from four to six feet deep. This cut is made on a level with the floor, being of a V shape, eight inches in front and tapering back to two inches in the rear, making an average cut of five inches. When the under cut is made, the operator in like manner can shear the ends. One great advantage of this V-shaped cut is that, when the coal falls it will roll over and out of its original position, where it can be very advantageously loaded. It requires one man and helper to operate the machine.



Michale's Mining Machine. Side view, with one half of the machine proper removed.

The machine has been thoroughly tested in the hardest coal in Western Pennsylvania, and the results have been of a most gratifying nature.

PRESIDENTIAL ADDRESS TO THE LIVERPOOL PHYSICAL SOCIETY.*

BY PROF. OLIVER LODGE, D.SC., LL.D., F.R.S.

We meet here as a working society of members, all alike interested in physical science and willing to study seriously the enormous groups of phenomena which that term covers. Our subject is a most enticing one, but it is alarmingly huge. No man can pretend to be equally familiar with all parts of it, and with all its border sciences. Yet, to be a complete physicist, that is what is demanded. As the German proverb says, "Ein Physiker muss Alles kennen," and the hopeless impossibility of satisfying such a demand ought to brace us to fresh effort rather than to unnerve us with slackened energies. Such a demand, moreover, has the happy equalising effect of the theological doctrine of original sin and free grace: it makes us all alike incompetent and unworthy; and since no man is able to proclaim himself a complete physicist, every man who takes up and works at one corner of it may hope for some result from his labours, if he pursues them in a patient and candid and undogmatic spirit. With those persons—paradoxers, as De Morgan called them—who, on the strength of a few ill-considered notions, propose to reconstruct the universe, and to flout their conceited ignorance in the face of the great searchers after truth of all eras: with them, I was going to say, we have no patience. But patience one does have with them nevertheless, for they are frequently unhappy and misguided men, not without a certain ability, possessors often of a very enviable energy; men who, if rightly self-directed, might have accomplished something, but who, by reason of some trivial crank, continue all their lives to batter themselves fruitlessly against the hard wall of opposing fact, flattering themselves that they are attacking a malicious combination of unprincipled scientists, banded together in league against them.

Such are the men who say that the earth is flat, that electricity and heat are identical, that water is a form of energy, that the circumference of a circle is commensurably related to the diameter, and so on. Men, again, who assert that they have discovered a new force, and that the nature of electricity has revealed itself to them, after reading some three-and-sixpenny text-book on the subject. Such persons should be informed that what they have found in an elementary text-book is but the A B C of the subject, and for them to presume to have a first-hand opinion on it is as absurd as if a person who had read nothing but a few pages of English Grammar, should propound opinions on English literature, and write an essay on the works of (say) Mr. Browning. Not such, however, are the men who ever advance science. The unprofessional workers are patient humble men, who grope their way, occasionally by means of mathematics, more often by means of experiment; searching diligently and recording their results, guided by instinct often more than by knowledge, knowing indeed it may be very little, and making many mistakes, but perseveringly amending their methods and devising fresh ingenuities of attack. To some of these it is occasionally given to discover secrets hidden from the wise and prudent. A trained mechanician, for instance, has immense advantages in the command of tools and weapons of investigation. Such workers have often a deftness of hand, a keenness of eye, and a delicacy of touch, which those who have had more time and opportunity for study have good cause to envy. And their very lack of a wide outlook, by leaving them leisure and will to concentrate attention on one small corner of the field, may result in their detecting treasure unsuspected by the man of broader views. Continually it has to be noticed that the most novel and surprising facts are discovered, not by the man of learning, who is apt to be over-weighted by his stores of information and to move rather cumbrously in unexplored territory, but by the light skirmisher or adventurous explorer, who penetrates with apparently inadequate equipment into wilds and thickets regarded as scarcely penetrable by the more completely panoplied general of modern science.

I will now see what useful suggestions I am able to make concerning fields of work lying open to the explorer at the present time. Needless to say that those I do not see or at the time think of are more numerous by far than those I mention, but, standing up and looking about, I see a number of likely-looking avenues which may lead to something if followed up; all that is needed being a good head, patient labour, and persevering skill to bring facts to light now only dim and unknown. Some of these avenues I will now do my best to point out; and though, no doubt, some are blind alleys if pushed into straight ahead, it is wonderful what side issues and unexpected openings present themselves when once you have set out on a quest. This is the great advantage of a study of nature. You may, by ill-luck, start with erroneous ideas, and may be aiming after something impossible to attain; but if you keep your senses open by the way, the things you will

* Delivered at the Inaugural Meeting held on December 16, 1889. Abstracted from *Research*.

Digitized by Google

unexpectedly hit upon turn out far more interesting and really valuable than the chimera in quest of which you started.

Running over some of these open paths we come across a fruitful field in a study of the effects of light on a great number of things. That light affected chemical combinations has long been known, and it is the foundation of photography, but we now find there is scarcely anything which light does not affect. It affects solenium enormously, bringing down its electrical resistance to half or one-third what it is in the dark: it may affect other bodies in a similar way. It affects metals, charging them electrically in a curious way, especially such metals as zinc. It seems to disintegrate or evaporate surfaces long exposed to it. It affects the electric field, causing a short spark to occur much more easily in ultra-violet light than in the dark. And quite recently, by Mr. Shelford Bidwell, it has been found to affect the magnetism of an iron rod in a sensitive condition. Of none of these phenomena has the investigation more than begun. Then, in the region of photography, there is a good deal to be done not only in understanding the photographic process itself, but in photographing rays hitherto intractable. The photography of ultra-red rays a good way below the visible spectrum is, so far as I know, in the hands of Captain Abney, who discovered how to do it. But others should now take it up and develop it. Celestial photography, with plates sensitive to obscure rays, might reveal a number of unsuspected and invisible semi-cool worlds. The electric spark has lately been a favourite subject for photography, and much good work may be done by obtaining judicious photographs of lightning on fixed and on moving plates. A double-nozzled camera, with two plates, one fixed, the other spinning rapidly on an axis perpendicular to its plane (kept spinning at an approximately slow speed, say by clockwork), so that the same flash is depicted on both plates simultaneously, would give much valuable information. For some flashes a very moderate speed of rotation, or even a waggling camera, suffices, but for others a speed of 30 revolutions a second gives an image apparently the same as if the plate were still. What is known as the Hall effect in various substances has not yet been exhaustively observed or measured. It has not even been observed as yet in insulators, though it ought, one would think, to be there; nor has its connection with the Faraday effect, the rotation of the plane of polarisation of light by magnetism, been at all satisfactorily or finally made out; while its discrimination from, or assimilation to, certain known thermoelectric facts is at present hanging in suspense. Perhaps, however, these matters are rather too complex to be suitable for mention under present circumstances.

A simpler and more qualitative research is the effect of magnetism on a number of things. For instance, on living organisms. A person in a magnetic field is not known to feel anything. Reichenbach thought he had found people who were optically sensitive to a magnet, so that they could see whether an electro-magnet is excited or not. It may be so, but subsequent observation has not gone to confirm it. But, even if all persons are insensitive (by no means a likely conclusion without experimental proof), other animals may not be. Phosphorescent things—a glow-worm, or some of the luminous sea beasts of Dr. Herdman—may be fit subjects for experiment. How, again, does a gymnotus or electric eel behave in a powerful magnetic field? I can imagine a fine field for a physicist to encamp on Puffin Island, under the auspices of the Biological Society, and bully some of the microscopic and other animals with electric and magnetic and optical appliances. Even if they declined to take any notice, the fact ought to be ascertained; but if any of them were properly sensitive, development of the fact might be surprising. Then, again, plants: sensitive and other muscular plants are well known to set up electric currents and to be under electric control; magnetism might be applied to plants also; and about their electric phenomena there is much more to work out. Heaps of experiments on plants and on germinating seeds could be made by an ingenious physical experimenter, and, though they might be more sluggish in their response than animals, some remarkable development might ensue. A change of physical surroundings in the course of a few generations might bring about noteworthy changes of structure. Seeds growing under inverted circumstances as regards light have, I suppose, already been experimented on. I do not know. I am not familiar with the subject, and the biological suggestions I throw out are therefore vague. But this I feel, that so long as the origin of life is wrapped in mystery, experiments on the simplest form of protoplasm—subjecting it to a variety of kinds of circumstances, electrical, magnetic, optical, thermal, mechanical, and chemical—may any day, though not perhaps for a few centuries yet, result in an astounding discovery, which will throw our present idea of evolution into the shade.

A number of experiments and observations can also be made on crystals and crystal formation by those who have suitable opportunities. The accidental formation of twin crystals, and the beautiful optical phenomena which develop themselves at the twinning surface, are matters of quite recent discovery, or, at least, of recent attention. So also is the perfectly astounding fact that a crystal, such as Iceland spar, for instance, can be mechanically twinned or pushed over into its perverted form by the pressure of a knife judiciously applied. Effects of magnetism on chemical action have now been discovered, and it is known that a piece of magnetised iron is less easily attacked by an acid than ordinary iron, provided, at least, the iron is pointed so that its lines of force are very diverging, or its field rapidly varying. But many other facts remain to be ascertained in connection with these subjects. The electrical properties of flame are only partially worked out, and their power of discharging static electrification has had fresh light thrown on it quite lately by some experiments of Worthington. The study of phosphorescent substances is yet in its infancy. Why should not a phosphorescent substance give out a really useful amount of light? What is the process by which the glow-worm maintains so brilliant a speck of illumination?

Many amateurs possess an induction coil, having, indeed, often made it themselves. Approximately the same number of amateurs do not know what to do with it when made. They use it to illuminate vacuum tubes, which they buy at a shop, nicely coloured. Well, don't buy them, but make them, and omit the colours. Read the researches of Mr. Crookes, and other more recent investigations on the subject by Schuster, and Moulton, and E. Wiedemann, and others, and you will find in the electrical phenomena of high vacuum an unlimited field for profitable experiment. More than this: a whole continent of practically unexplored territory has just been opened by the discovery of Hertz that electro-magnetic waves in air can be easily produced and detected. Some may know and some may not know of these brilliant investigations into the propagation of electro-magnetic waves. To those who do not know I can give no idea in the course of this address. I am dealing with them in my evening course throughout next term. But anyone with an induction coil, an empty room, and some bits of metal can repeat many of them. And repetition of known experiments is the natural prelude to the discovery of new ones. The Hertzian receiver is a microscopic spark gap. This serves, but it is by no means necessarily the best, as it is certainly not the most metrical method. Gregory has tried a kind of metallic thermometer with some success. In Germany, I hear a kind of bolometer or wire resistance thermometer has been successfuly used. Quite lately, Fitzgerald writes me that a galvanometer in circuit with a simple wire makes these waves apparent. This will simplify their investigation very much. That is always the way. Once a thing has been done, hundreds of ways of doing it turn up. For instance, the telephone. The transmission of speech by electricity seemed a mighty achievement, and so it was; but now, almost anything will transmit speech—a flower-pot full of cinders has been made to talk. The great electro-magnetic waves excited by any kind of electric discharge are now under easy control, and they can be reflected by mirrors, refracted by prisms, concentrated by lenses. They can be polarised and analysed. Diffraction and interference effect can be detected in them. Everything optical has its counterpart in this new region, for they are to all intent and purposes Light: as Clerk Maxwell predicted nearly a quarter of a century ago, from refined and abstract mathematical investigation.

The whole of this great field now lies open to the explorer, and only a few have entered it. Here and there a mathematician, here and there an experimentalist, is at work upon it, but there is plenty of room, and every fact is of interest. These electric waves have been obtained as long as 2,000 miles and as short as a foot; they can easily be lengthened, they cannot so easily be shortened. If shortened to the 10,000th of an inch they would affect the retina and be visible. At present they belong to the region of the infra-red. Whether they affect the human frame at all is unknown. Apparently they do not, but further experience may show that they do. Here also is a scope for observation. This is a good era for the formation of a Physical Society. That there is no time like the present is true, and true always, but it has been doubly true in science during this nineteenth century. Abused we have been; much of our work has been divorced from art and culture, and some of our works are hideous. The foghorns, with which we shall shortly frighten in the new year, are unspeakable; but, for better or worse, the nineteenth century has been the century of science. Never has there been such an increase in knowledge in material achievement; never have so many secrets of nature been unveiled. We inherit the fruits of all this labour, we live encompassed by it—by the evil as well as the good—the smoke-canopied, overcrowded, and squalid towns, as well as the bright and beautiful ideas which this century is responsible for; and it remains for us to enter the twentieth century not abandoning the good but doing our best to remedy some of the evil, and to hand on the at present rather smoky torch of science burning the clearer and the brighter for our life and work.

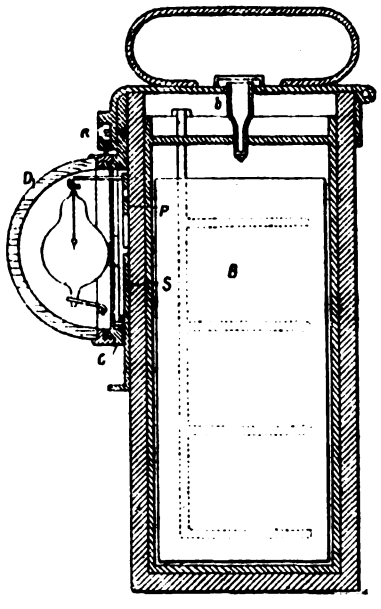
BRISTÖL'S PORTABLE ELECTRIC LAMP.

In the figure below we illustrate a neatly arranged portable electric lamp devised by Mr. L. Bristöl. The lamp is particularly applicable for use in dangerous situations, such, for example, as coal mines, powder mills and magazines, chemical laboratories, &c. The current is provided by an accumulator inclosed within a polished wood box, on the face of which, for the above purposes, the lamp is fixed within a strong glass dome, D, and backed by a reflector. The box has a metal lid with a projecting lug, which covers one of the charging terminals, so that when the lid is closed the battery cannot be short-circuited. The lid also carries a lock, *a*, by which it can be secured; a pin on this lock fixes the glass dome against being unscrewed. The holders of the glow lamp are attached the one to the positive terminal P of the battery, and the other to an independent plate, between which and the negative terminal of the battery circuit is made and broken by the spring sliding switch S passing through a groove behind the plate C.



The battery plates B are of special construction, designed to give them such a degree of self-cohesiveness and rigidity that no additional metallic support is required. There is mixed with the active material a suitable proportion of fibrous substance, and the whole is made into a paste. This is cast in moulds, a conductor being inserted in each plate to aid the flow of the current. The plates are then gently pressed and dried. A hollow plug, *b*, is provided for the escape of the gas given off during charging.

The following are some data with regard to these lamps.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

April 9, 1890.

The Exhibition of the Société de Physique took place on Tuesday and Wednesday last in the rooms of the Société d'Encouragement. Amongst the new apparatus I noticed an absolute condenser, with guard-ring, by M. P. Curie. This condenser consists of two glass plates, very carefully faced, one side of each plate being silvered. On one of the silvered faces a circle, having a diameter of 6 centimetres, is traced with the compass, the line traced being $\frac{1}{15}$ of a millimetre thick; and in this way a disc of known geometrical dimensions is insulated from the rest of the plate, which constitutes the guard-ring. A little hole pierced in the centre of the circle allows a wire to be connected to the terminals of the apparatus. The other side of the condenser is formed by the second silvered glass plate. Upon the lower plate are three little glass supports, the thickness of which is carefully determined by a spherometer, and on the top of these glass supports the first plate rests with its silvered face underneath. We thus have an absolute condenser, whose capacity is determined from its geometrical dimensions. Amongst the other new apparatus, I noticed a resistance-box for commercial purposes, in which the arms of the bridge can be quickly altered by turning a handle, and a Thomson bridge by which one can easily measure $\frac{1}{10000}$ ohm in testing the conductivity of copper wires. There was also to be seen one of M. le Châtelier's pyrometers, consisting of a long iron tube enclosing a thermo-electric platinum—platinum-rhodium couple, contained in a tube composed oi a refractory earth; the apparatus also comprised a Deprez-d'Arsonval galvanometer, the suspending wires of which can be rapidly changed in order to vary its sensibility. These three instruments were shown by M. J. Carpentier. M. E. Ducretet showed a pretty little instrument for repeating the experiments of Elihu Thomson. The apparatus consisted of a balance, one pan of which was replaced by a coil of wire connected to a small lamp, and in the centre of this there was a fixed coil connected to an alternate-current machine. When the primary circuit is closed the lamp is lighted, and the equilibrium of the balance is disturbed. To restore equilibrium it is necessary to take weights out of the opposite pan. M. Ducretet also showed a large Wimshurst machine, having 12 plates 75 centimetres in diameter. Besides these new instruments there were a large number which, although not absolutely novel, were nevertheless of some interest. Amongst these I may mention a Deprez-d'Arsonval ballistic galvanometer, which comes to rest the moment it is short-circuited; a megohm divided into ten resistances of 100,000 ohms; a large-deflection (180 deg.) D'Arsonval galvanometer, the scale of which is graduated in milliamperes for electro-therapeutic purposes; some remarkably fine photographs of lightning flashes, by General Sébert; a Curie-Blondlot astatic electrometer; and some Reynard batteries. Considering the short time which has elapsed since the closing of the Universal Exhibition, the show of new apparatus was remarkable.

At the last meeting of the Société Internationale des Électriciens M. Hospitalier raised some objections to the methods of measuring used at the Laboratoire Central d'Électricité, and described at a previous meeting by M. de Nerville. M. Hospitalier objected principally to the alternate-current measurements, which are effected by means of an electro-dynamometer and an electrometer as if there were no difference of phase between the current and E.M.F. curves. M. Hospitalier further urged that the specific resistance of wires sent to be tested should always be given, and not their conductivity; since the conductivity of a wire is very different according as it is compared with that of another pure (Matthiessen) copper wire of the same volume or of the same mass; moreover, as he remarked, copper may now be obtained by the Elmore process and by other means with a conductivity of 110 per cent. M. de Nerville quite agreed with M. Hospitalier, but stated that he was obliged to conform to the regulations; however, whenever possible, he would state the results in specific resistances. At the same meeting M. Minet gave a detailed description of his process of obtaining aluminium direct by the electrolysis of fused fluoride of aluminium, and showed some fine specimens of pure aluminium so obtained.

The Gare de l'Est, with the exception of a few offices, is now lighted throughout by electricity. The installation comprises 158 Cance arc lamps and 1,100 15 candle-power incandescents. The three-wire system is employed, the dynamos being mounted on the same bed-plate. The Cance lamps are run off a 65-volt circuit.

CORRESPONDENCE.

ALTERNATING v. CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Please allow me, for my colleague, Dr. Harries, and myself, to reply to the letter of Prof. Forbes, which you published last week.

That there is truth in the statement that the alternating currents from a dynamo differ from those produced by an induction coil, it would be folly to deny; but the extent of that difference, and its *effect upon the human body*, is another matter.

Unfortunately for his case, Prof. Forbes proves too much. He writes:—"The instrument employed measures the *effective* current." . . . "The discomfort measures the *maximum* value of the current;" and further, "Thus the current which caused discomfort was probably *20 to 50 times* the current measured."

If these statements be true, taking his lowest estimate of maximum current, and, therefore, according to him, of *discomfort*, the alternating current which in our experiments produced discomfort was $1{\cdot}7 \times 20 = 34$ *milliamperes*. On the other

Digitized by Google

hand, Prof. Forbes appears to accept our discomfort figure for continuous current, viz., *10 milliamperes*; but the Professor himself stated at the meeting that he *knew* he could not bear nearly as much alternating as continuous current; and several other speakers confirmed this.

As shown above, his letter attempts to prove that it takes *more than three times as much alternating current as continuous to cause discomfort.* In the days of Euclid this would have been called a *reductio ad absurdum*; but in the present day we need only adopt Prof. Forbes's own phraseology, and term *his* error a "fallacy."

In considering the effect upon the body of possible difference between maximum and effective alternating currents we have to take into account potential counteracting effects of increased rates of alternation. Our experience so far is that the slower the rate of alternation the greater the discomfort for the same current strength. Our Paper dealt with a higher rate of alternation than that commonly in use in light circuits. It is therefore highly probable that the increased discomfort which would be produced by the slower alternations of a dynamo circuit would more than counterbalance the possible difference between effective and maximum current due to the use of an induction coil of much more rapid alternation.

Electricians generally show too marked a tendency to look upon the human body as an inanimate conductor, and to apply to it the same laws. I need hardly reiterate what Dr. Harries insisted upon in his reply at the meeting, that the physiological conditions controlling the resistance of the skin make all the difference in the results of contact.

Our Paper deals exclusively—as we mentioned therein—with phenomena *after* contact, and deliberately excludes from consideration factors involved in bringing about that contact.

We desire to emphasise the difference between *resistance* and *sensation*, and trust that in future this important point will not be lost sight of.

As indicated at the meeting, we have further investigations in progress, and therefore forbear entering now more fully into the points raised.—Yours, &c., H. Newman Lawrence.

ELECTRIC LIGHT INSTALLATIONS AND THE MANAGEMENT OF ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: May I be permitted to say a few words bearing upon your friendly criticism of my little book?

The errors you point out are mainly due to general language; but in another edition I will be more explicit. The B. T. unit given as 1,000 watts, instead of 1,000 watt-hours, is evidently an oversight, as are also a few more similar errors here and there in the book, many being the fault of the printers.

One serious mistake exists, but it was discovered by me when too late. The notes upon the ohm-meter were dictated when describing the watt-meter, hence this instrument is wrongly described.

In the sixth edition these faults will be corrected, and many new points added, including a full description, with plates, of Messrs. Goolden's testing apparatus—whose permission has been asked and kindly given; also the practical way to make and insulate joints, at the suggestion of Sir Richard Webster, who considers much ignorance exists on this head. I may say that when the fifth edition was published Messrs. Goolden's tester was not made, so I gave the methods of testing followed by the London Electric Supply Corporation.—Yours, &c.,

49, Grosvenor-street, W., April, 1890. David Salomons.

DYNAMO AND MOTOR DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

Sir,—In your issue of the 4th inst. a letter appears under the above heading from Mr. W. B. Sayers, in which he complains that the "authorised abstract" of his remarks is "incomplete and misleading." Perhaps you will allow the writer of the abstract to express his great regret that cause for dissatisfaction should have arisen, and to add a few words of explanation. First, as regards "incompleteness." This I admit, for all abstracts are necessarily incomplete.

Next, as to being "misleading," I am willing to admit that the abstract may not express exactly what he intended to convey; but I think Mr. Sayers has himself to blame for not having made his meaning sufficiently clear. This opinion is supported by the fact that he has found it necessary to re-write his remarks before they are printed in the "Journal." He has also thought it desirable to add an "explanatory note" to his contribution, in which he puts his meaning much more clearly than it is given in the verbatim report of what he said.

In this note he also says, "the explanation given by Mr. Swinburne in his reply to my remarks related only to the action which takes place *when the brushes are in the non-sparking position*, and agrees precisely with my statement of the case." This shows that even Mr. Swinburne had not properly understood the "true purport" of what Mr. Sayers said, otherwise he would not have given as his own an explanation which Mr. Sayers had propounded a week previously.

I take this opportunity of pointing out some typographical errors in the abstract of the discussion, as printed in your journal.

Page 528, column 1, line 47, *for* "non-resistance" *read* "non-existence."

Page 528, column 1, line 9 from bottom, *for* "bands" *read* "hubs."

Page 529, column 1, line 5, *for* $\frac{Z\,d}{Z\,\delta}$ *read* $\frac{Z\,d}{2\,\delta}$.

—Yours, &c., The Writer of the Abstract.

THE VILLARI CRITICAL POINTS OF NICKEL AND IRON.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of last week there are two corrections in the report of my Paper on the above subject which I will ask you to be so good as to make: (1), the diameter of the nickel wire used was 0·8 m.m., not 8 m.m.; (2), Mr. Shelford Bidwell pointed out at the end of the reading of the Paper that I had not quite understood some remarks of his respecting the conclusions of Prof. J. J. Thomson. Prof. Thomson did not conclude that a Villari critical point for nickel *could* not exist, but only indicated the *probability* of its non-existence.—Yours, &c., Herbert Tomlinson.

36, Burghley-road, Highgate-road, N.W.

MORE LIGHT ON ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have just completed experiments which prove that a surcharge of electricity, on passing though the glass of a Leyden-jar by conduction, alters the attraction of cohesion of the glass; so that when the jar is fully surcharged, the attraction of cohesion of the glass is then five hundred and fifty times greater than it was before the surcharging commenced.

I also find that the specific increase of the attraction of cohesion caused by a surcharge of electricity varies according to the nature of the substance operated on, and hence there is now a door opened for our understanding the Peltier effect and other electrical phenomena which have hitherto been inexplicable.—Yours, &c., James Johnstone.

8, Murchiston Park, Edinburgh, April 2, 1890.

WORD-COINING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Could there be a more appropriate word to indicate travelling by electric power, or one which more thoroughly meets Lord Bury's excellent suggestion, than to *Faradate*? which in French becomes Farader, in Italian and Spanish Faradare and Faradear, and in German Faradiren.—Yours, &c.,

April 10th. O. C. D. Ross.

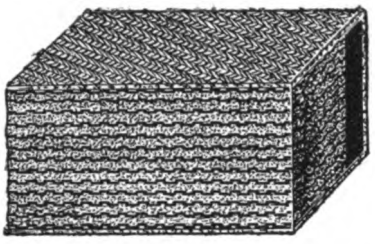
"DURIFLEX" PACKING.

Messrs. David Moseley and Sons, of Manchester, have introduced a new engine packing, to which they have applied the trade mark "Duriflex." The object of the manufacturers has been to combine the durability of a metallic with the flexibility of a fibrous packing. "Duriflex" packing is especially applicable where long



runs are a necessity, and for use in high-pressure engines. The packing is constructed in a peculiar manner from wire and a fibrous material such as asbestos or cotton, and from the nature of its construction it follows that it must possess the qualities of durability and flexibility in a high degree. It may be constructed in any form and with or without indiarubber cores; but the ordinary forms represented in the engravings are generally used. In the engravings the wire gauze is indicated by

Round core.

Round rope.

the thicker black lines. This is prepared before insertion in the packing by cutting or corrugating it diagonally and by placing it between the layers of fibrous material with the cuts or corrugations diagonally arranged. By this means the rigidity of the wire gauze is entirely destroyed, and the packing has as great a flexibility as similar packing made entirely of fibrous materials.

TRADE NOTES AND NOTICES.

THE UNIVERSAL ELECTRIC TELEPHONES.—We are in receipt of printed particulars of the Universal Telephone, manufactured by the Universal Telephone Company, who have recently taken premises at 11, Queen Victoria-street, London, E.C. Illustrations are given of several patterns, including the pedestal telephone, the pocket telephone, the domestic telephone, and a telephone for office and general use. We are informed that a large number of these telephones are already in use, and the prices quoted for complete sets are very reasonable. The Company are prepared to undertake the erection of telephone lines, and the supply of all descriptions of telephonic apparatus.

WENHAM COMPANY (LIMITED).—This Company announce that they have added to their business in gas lighting and ventilation an electrical department, under the supervision of competent engineers, and are prepared to undertake all kinds of lighting and engineering work. The Company also notify that Madame Adelina Patti's private theatre and winter garden at Craig-y-nos Castle are being lighted with the electric light, the whole of the work being carried out by the Wenham Company's staff.

ZÜRCHER TELEPHONGESELLSCHAFT.—We are informed that Herren Dr. Emil Blattner and Giovanni Mariotti have become associated with the directorate of this Company.

POSTAL TELEGRAPH AND CABLE COMPANY.—This Company has voted to increase the capital stock from £1,000,000 to £2,000,000, in order to pay Mr. J. W. Mackay for properties owned by him and worked by the Company.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

COMPANIES' MEETINGS.

The Brighton and Hove Electric Light Company (Limited).

The report of the Directors of this Company for the year ending December 31st says:—The capital account has been augmented by the sum of £3,860, which has enabled the Company to increase the capacity and efficiency of its plant and to re-arrange and insulate the greater part of the overhead circuits in accordance with the new regulations of the Board of Trade. The profit and loss account, after writing off an ample sum for depreciation of plant (which has, however, been kept in thorough repair out of revenue), shows a balance of profit for the year of £529. 10s. 10d., which, with the balance brought forward from last year's accounts, makes the sum to the credit of profit and loss account £557. 19s. 8d.; but in view of the lawsuit of "Garman v. the Company," the Directors recommend that no dividend be declared in respect of the profits of the past year. It will be noticed that there is a falling off in the profits, which is due to three causes:—

(*a*.) The loss incurred owing to the reduction of price from 1s. to 10d. per unit.

(*b*.) The heavy extra cost of running the machinery night and day during the first half-year.

(*c*.) The great advance in the price of coal, amounting to 7s. per ton.

The Directors confidently look forward in the coming year to the business of the Company at least yielding the former 5 per cent. dividend. The Directors greatly regret that, in consequence of the opposition of the Corporation of Brighton and of the Hove Commissioners, they have been disappointed in their efforts to obtain a Provisional Order under the Electric Lighting Acts, 1882 and 1888. They trust, however, that the Corporation's sense of honour will soon modify this opposition, and that this Company, which is quite willing to submit to any fair terms to be imposed by the Town Council, will not be subjected (after building up the business during the past seven years) to what would practically amount to an act of confiscation and ruin of the local business. The Directors hear that there is a growing feeling among the ratepayers against the town undertaking the business of supplying light to the wealthy and large industrial institutions in the borough, as the rates and the risks will fall upon all alike. Moreover, it is felt that at this stage of the electric light supply, the business has hardly passed out of the speculative category; and that a Cor-

poration can never work a business of this kind so economically as a Company like this, with its long experienced and skilled engineers and officials, and thorough acquaintance with the cheapest markets for plant and materials, and that the Corporation will be sure to "burn their fingers," and regret their action sooner or later. It will be remembered that in their last report the Directors advised the shareholders that this Provisional Order was being applied for at the special invitation of the Board of Trade; and at the local inquiry, conducted by Major Marindin, which was held in Brighton in April last, the Directors were confident that they had gained their point, but strong representations being made by the Corporation of Brighton of their intention to undertake electric lighting works themselves, the Board of Trade refused to sanction the Order last Session. Application is, however, being again made this Session, and the Company are confident of eventually either obtaining a Provisional Order or coming to satisfactory terms with the Corporation. If the Corporation carry out their plan of laying opposition works to the Company, the Directors are confident that, though this may prevent an immediate extension of the works, it will not materially injure the Company's present business, as their customers will still obtain their electric lighting supply from the Company; and whatever action the Corporation may take, it will not prevent the Company using and extending its present overhead circuit. Of course the Directors repeat the assurance, which they have from time to time given to the shareholders, that their desire is to lay the wires underground, but, until that is sanctioned by the Provisional Order consented to by the Brighton Corporation, they are compelled to continue their business by means of the overhead circuit. The Company has completed the alterations referred to in their last report, and at the present time the whole of the Company's supply is on the most modern system known, namely, the Converter System, by means of which the heavy waste connected with the use of accumulators is avoided, as well as the heavy cost in mains. The exact nature of the improvement in the Company's business may be seen by the following statements:—

Lamps supplied from the Company's mains on—

December 31, 1887, equivalent to 2,970 10 candle-power lamps.
" " 1888 " 5,500 " "
" " 1889 " 8,953 " "

Quantities of electricity supplied from the works during the past year, as compared with corresponding months of previous year:—

Units supplied.

	1888.	1889.		1888.	1889.
January	7,533	12,689	July	2,687	6,458
February	5,430	10,322	August	4,300	8,390
March	4,550	8,909	September	5,419	10,052
April	4,813	8,401	October	7,615	13,255
May	3,359	7,300	November	12,567	17,261
June	2,707	5,320	December	13,930	19,320

Total, 1888, 74,910 units; 1889, 127,647 units.

equal to an increase for the current year as compared with last year of 70 per cent. During the past year, Mr. Arthur Wright has resigned his position as Managing Director, and Mr. Albert Gay has been appointed in his stead to manage the works. Mr. Gay has already effected economies in working, and the Directors are highly satisfied with him. Mr. Thomas Webber Jerrard has been compelled to resign his seat on the Board owing to the extremely limited time at his disposal; the Board has, however, been strengthened by the election of Mr. Frank Wilden Bentley and Mr. Arthur Kimber. The Directors invited Mr. Kimber to join them, not on account of the amount of his monetary interest in the Company, but because he is a leaseholder and large ratepayer in the district, and is a Director of the Norfolk Hotel, and one of the largest proprietors of the Bedford Hotel, both of which companies are considerable consumers of the electric light. He will, therefore, be in a position to specially serve the interests of the consumers and ratepayers alike. If the Company obtains its Provisional Order, or comes to a fair arrangement with the Brighton Corporation, it will be desirable and agreeable to your Board to invite the Corporation also to appoint a Director to represent its interests and those of the ratepayers generally.

The retiring Directors are Mr. Robert Hammond and Mr. P. A. Latham, who offer themselves for re-election.

NEW COMPANIES REGISTERED.

ANDREWS AND PREECE (LIMITED).—This Company has been registered to carry on the business as heretofore carried on by Thomas Reginald Andrews and Thomas Preece, electrical engineers, of the Borough Mills, Bradford, Yorkshire, adopting therefor an agreement expressed to be made with the said parties, the particulars whereof are not specified in the Articles of Association. Capital, £25,000, in £10 shares, of which 300 are Deferred shares, to be allotted as fully paid-up to the vendors as part purchase-money for the said business, and upon which dividend is to be paid after 6 per cent. shall have been paid on the ordinary shares. Subscribers of one share each are: the vendors above named; Albert Hanson, electrician, Thornleigh, Apperley; John Henry Murgatroyd, Halifax; William Booth Brayshaw, draper, Manningham; Robert Charles Douglas, electrical engineer, Bradford; and James Duff, accountant, Bradford.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended April 4th amounted to £4,134.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of March show an increase of £253 as compared with the corresponding period.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of March were £41,133, as against £42,896 for the same period of 1889.

ELECTRIC WELDING SYNDICATE.—We understand that the Electric Welding Syndicate is about to launch a large company, with a capital of £460,000, to work the Thomson system.

ELMORE'S COPPER DEPOSITING COMPANY.—The Directors of this Company notify a dividend of 50 per cent., payable, one-half on April 18th and one-half as soon after June 30th as the accounts can be made up.

FAREHAM ELECTRIC LIGHT COMPANY (LIMITED).—The first general meeting of this Company was held recently at the Foresters' Hall, Fareham; Capt. Ramsey in the chair. Mr. James Blake, speaking of the Company's position, stated that a contract had been entered into between them and Messrs. Laing, Wharton and Down, the syndicate working the Thomson-Houston system. He thought the system would prove a beneficial one, and it had been adopted with much success in many parts of the metropolis. A contract for steam-power had been entered into with Messrs. Ransomes, Sims and Jefferies, of Ipswich, for engines of 105 indicated horse-power. They had authority from the Fareham Local Board to enter the town and erect all the necessary plant and appliances for supplying the electric light, subject to the rules and regulations of the Board of Trade. An advantageous site for building a station was at their disposal. He thought the Company would be able to supply the light generally to the town in about three months. A vote of thanks to the Chairman concluded the business.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of March amounted to £20,800. From the 1st January to 31st March these receipts amounted to £60,200, against, in the corresponding months of 1888 and 1889, £63,800 and £63,000 respectively.

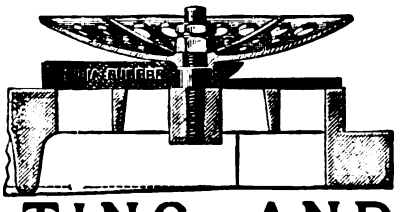
REUTER'S TELEGRAM COMPANY (LIMITED).—The twenty-sixth ordinary general meeting of the shareholders of this Company will be held on Wednesday, the 23rd inst., at noon, at the Company's offices, 24, Old Jewry, London, for the reception of a report and balance-sheet from the Directors, the declaration of a dividend, and the election of a Director and auditors. The transfer books of the Company will be closed from the 8th until the 22nd proximo, inclusive.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended March 31st show an increase of £21 as compared with the corresponding period.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended April 4th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,172.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 622.—Vol. XXIV. FRIDAY, APRIL 18, 1890. Price Fourpence.

NOTES.

Sir Frederick Bramwell's Paper on "Electric Welding" at the Institution of Civil Engineers on Tuesday night occasioned a remarkable degree of interest amongst the members, numbers of whom could not find room in the theatre. A formidable array of electric welding appliances gave promise of some large-scale experiments; but the most unique feature of the evening was the hammering of a 1⅛in. iron bar on an anvil by two smiths. What would Telford, Brunel, and Stephenson have thought of an anvil ringing and sparks flying from the actual welding of a large iron bar behind the president's chair?

The annual general meeting of the Electrical Trades Section will be held on Monday next. A good attendance is especially desirable on this occasion, as the business on the Agenda Paper includes the election of chairman, deputy-chairman, and committee. It is intended, we understand, to increase the committee from 33 to 48, the number originally proposed.

Mr. Melhuish's Paper "On Signalling across Rivers in India," read at the Institution of Electrical Engineers last Thursday, and which we print this week, is a notable contribution to practical telegraphy, applicable not merely to India, but probably to countries nearer home. The methods employed in the experiments were novel and highly successful, whilst the utilisation of Cardew's vibrating sounder in connection with the sheaths of submarine cables adds one more useful purpose to which that valuable little instrument can be put when ordinary means of communication fail.

After having had an Earl and a Baron to espouse their cause in Parliament—to say nothing of Mr. Redmond and Dr. Tanner—the telegraphists ought to be satisfied that their grievances are receiving highly distinguished, if not very discriminating patronage. Those grievances, so far as they had been previously brought under the Postmaster-General's notice, and on which we commented a week or two ago, are being treated by him just as we suggested they should be. A committee is sitting to inquire into the nature of some which are capable of amendment, and into the reality of others which are of doubtful accuracy. As to the rest, Mr. Raikes frankly told the House of Commons that the demands could never be conceded, and we should say that the telegraphists knew this perfectly well beforehand. One complaint, however, which was strongly dwelt upon by Earl Compton, did not find a place in the public manifesto, namely, the long hours the men were sometimes compelled to work as overtime. No doubt they would like it to be more evenly distributed—so would everybody who works overtime; but we doubt very much whether the telegraphists desire to have their earning power diminished; and, like all other wage-earning classes, they must take the extra duty as it comes, or sacrifice it altogether. With one exception, apart from a few trivial details which may be easily set right, we are still unable to discover any substantial grounds for all this agitation. The exception is in the distribution of the day's work. Extra duty is extra duty, and ought to be paid for in cash, not in release from duty at another time.

We publish this week some further details of Dr. Louis Duncan's tests of Westinghouse alternate-current apparatus alluded to by our New York correspondent in his letter of March 22nd. The efficiencies, although not so high as some recently "figured out" in connection with Ganz plant, are probably more like those which obtain in actual practice. A higher efficiency at full load than 78 per cent. may reasonably be expected from a modern alternator, and in the latest types of Westinghouse machines softer iron and better lamination have no doubt reduced the somewhat excessive loss in the armature core brought to light by these tests.

Some four months ago the Paris Municipality, it will be remembered, requested their technical advisers to inquire into, and report upon, the alleged infractions of the municipal regulations relating to the employment of foreign plant in the Paris central lighting stations. This report was presented last week and discloses a state of things which has aroused the indignation of all true patriots. The Edison Company, *horribile dictu*, have no less than four Babcock and Wilcox boilers, the ends of which are of metal of foreign origin. The worst offender, however, is M. Victor Popp, whose engines have all been obtained from abroad. These and other instances of free trading have resulted in a drastic municipal edict. Within three months all the foreign steam plant in the Paris central stations is to be replaced by French plant. M. Popp's air-compressing and compressed-air engines are, however, given twelve months' grace. Foreign dynamos are to be allowed to stay where they are, but the currents generated by them will not be permitted to mingle in fraternal union with French currents; for in Article 3 of this remarkable decree it is stated "that

Digitized by Google

the currents generated by electrical machines built abroad are not to enter the private-lighting mains;" and Article 5 forbids connection with the service mains until the Commission Technique has ascertained that all the plant of a central station has been manufactured in France. M. Popp has already stated his inability to procure satisfactory compressed-air plant in his own country; and if the Dandeu-Naze machine is a fair specimen, there would seem to be much the same difficulty with regard to large alternators. Municipal meddling bids fair, therefore, to prove as detrimental to electric lighting progress on the French as on the English side of the Channel.

We have received a communication from Mr. Keeley, of Ottawa, in reference to our article on his proposed system of working long submarine cables, which appeared in *The Electrician* of December 20th last. Mr. Keeley denies that there is anything in his specification which indicates a want of knowledge of the laws governing the transmission of currents. We think it only necessary to say, in reply, that the expressed object of his proposed system is to *eliminate retardation*, and that "polarised receiving instruments are called for under his invention." Mr. Keeley refers to a cable company which has in operation, on a 500-mile circuit, a polarised relay working with the greatest facility, and we also are aware of an instance where a polarised relay, after working well for many years, on a cable 620 miles in length, was aban doned for a recorder. Neither of these cases, however, proves anything with regard to a cable 1,000 miles in length, and still less in respect to one of the Atlantic cables.

On reference to the conclusion of our article Mr. Keeley will see that we did not imply, as he states, that he "proposed sending reversed currents from the transmitting end," that being the feature of another system, certainly not Mr. Delany's, as he assumes, which we said was similar to Mr. Keeley's in *other respects*. Mr. Keeley's letter concludes as follows:—"The *distinctive feature* of my invention is the application of a commutator at the *receiving* end of the circuit, whose alternating currents operate to neutralise or augment the currents emanating from the transmitting end, and the polarity of the latter is what determines the position of the needle or lever of the receiving instrument." From this and the following excerpt, those of our readers who are acquainted with the working of submarine cables will form their own opinion as to the probability of success on long cables of Mr. Keeley's system:—"The application of current to *both ends* of a cable gives rise to new conditions—that is, *different* from what is observed with currents applied at one end alone as heretofore." It is no doubt adaptable for land-line working, but instruments are at present in use over which Mr. Keeley's invention does not show any superiority, and we are unable to modify our views with respect to his system as applied to submarine cable work. This is a subject which has received a vast amount of attention from the leading telegraph engineers throughout the world, and we should be very pleased if Mr. Keeley should yet succeed in overcoming what appear at present to be insurmountable difficulties.

The liquidation of the Submarine Telegraph Company's affairs is now virtually completed; and whatever may be said of its management as regards the closing period of its existence, there can be no question as to the prudent and far-seeing policy pursued during the years preceding. A large reserve fund was accumulated, and invested so advantageously that the securities have been sold at a profit of over £26,000; and after paying off the shareholders in full there remains a balance to be distributed, after all claims are settled, of probably little short of 8 per cent. of the capital. The shareholders, although to be commiserated on the compulsory sale, may be congratulated, all things considered, on the final result. We are sorry to add that the same cannot be said of their employés, many of whom have been treated rather shabbily by this wealthy corporation.

By Section 4,887 of the Revised Statutes of the United States it is enacted that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than seventeen years." As our readers will recollect, the question as to what was meant by expiry at the same time as the foreign patent has been the subject of several contradictory decisions in the United States Courts. The matter is one of especial interest to American electricians, since a number of Edison's leading incandescent lamp patents are concerned. In January, 1889, the United States Supreme Court rendered a decision on this point, in the case of the "Bate Refrigerating Company *v.* Hammond;" and a still more conclusive judgment has just been given by the same Court in another patent action of a similar kind. In their last judgment the Supreme Court clearly state that the words "expiration of term" do not mean expiration of term through a forfeiture by breach of a condition, but mean expiration by lapse of time. Thus an American inventor who takes out a patent for his invention in Germany is by this decision no longer liable to forfeit his American patent because, for instance, he fails to pay the annual increasing tax required by the German law, and thus allows his patent in that country to lapse. The American patent is now held to run for the full term of years expressed on the face of it. This decision seems to be in accordance with the spirit of the statute and with common sense.

An important decision in connection with an electrical patent has also recently been rendered in the United States District Court, where it has been decided in an action between the Brush and Julien Companies that the Brush storage battery patent covers every battery in which the active material is applied to the plates by mechanical means. In November last, it will be remembered, the Electrical Accumulator Company obtained an injunction against the Fourth Avenue Railroad, who were running some Julien accumulator cars, which prevented that Company from using cells in which the active material had been applied to the plates in the form of a "paint, paste, or cement." This little impediment was promptly overcome by the Julien

Digitized by Google

Company, who set to work to make plates in which the active material was applied in the form of *powder*, and submitted to an enormous pressure. The latest decision, however, seems to cover the whole ground, and it is needless to say that an action is now pending between the Brush Company and the Electrical Accumulator Company.

Cordova.—The public lighting of Cordova by means of 180 arc lamps will be commenced on May 1st next.

The Rating of Machinery.—The Rating of Machinery Bill was read a second time in the House of Commons on Wednesday night.

Hanover.—From the *Elektrotechnische Zeitschrift* we learn that the authorities of Hanover have rejected the electric lighting proposals of the Popp Company.

London Chamber of Commerce.—At the last meeting of the London Chamber of Commerce, Sir Albert K. Rollit, M.P., was elected Chairman for the ensuing year.

Plymouth.—At a special meeting of the Town Council, held on Wednesday, consent was given to the application of the Devon and Cornwall Electric Supply Company for a Provisional Order.

The Lighting of the City.—A deputation, consisting of ten members of the London Commissioners of Sewers, visited Taunton on Friday last to inspect the public lighting by electricity.

Wandsworth.—At a special meeting of the Wandsworth District Board held last week, consent was given to the application of the House-to-House Electric Light Supply Company for a Provisional Order.

Rapid Telegraphy.—On March 5th Mr. Lee Cook, of Mexico, received a telegram with reference to the Pan-American Congress, containing 1,369 words, in less than two hours after it was handed in at Washington.

Telephonic Extensions.—On Tuesday last week the National Telephone Company celebrated the opening of their Dumfries and Carlisle trunk line, which opens up telephonic communication with Carlisle and West Cumberland.

Electrical Oscillation.—On Wednesday evening Dr. O. J. Lodge delivered an interesting lecture to the Glasgow Philosophical Society on "Electrical Oscillation." Prof. M'Kendrick presided, and there was a large attendance.

Royal Society.—At the last meeting of the Royal Society, amongst the Papers down for reading was one by Profs. Rücker and Thorpe, F.R.S., "Preliminary Note on Supplementary Magnetic Surveys of Special Districts in the British Isles."

The French Exhibition.—The exhibits at the forthcoming French Exhibition at Earl's Court are divided into 11 groups, Class III., Group IV., being partly devoted to electricity. The Exhibition will be opened on Saturday, May 10th, by the Lord Mayor of London.

Edinburgh Exhibition.—At the last meeting of the Executive Council it was announced that the Duke of Edinburgh had consented to open the Exhibition on May 1st. It was decided to build an additional annexe of about 5,000 square feet, to accommodate the French electrical exhibits.

Telegraph and Electric Wires in Canada.—The Great North-Western Telegraph Company of Canada have decided to protect its wires from crosses with electric light wires, and have issued general orders to its linemen to string a dead wire above their wires at all points where the same are crossed by electric light conductors of any kind.

Hertford.—At a recent meeting of the Town Council a resolution refusing to consent to the Provisional Order of the Hertford Electric Light and Power Supply Company was adopted; and the Council resolved to make an application itself, and to enter into an agreement with the Company to lay down the installation and supply the light.

Scarborough.—The Board of Trade has requested to be informed as to what steps have been taken by the Corporation to give effect to the powers contained in their Provisional Order, or if no such steps have yet been taken, to be furnished with some further assurance as to the time within which the Corporation are prepared to commence the supply of electric energy under their Order. It has been resolved to inform the Board of Trade that the Corporation are prepared to undertake to put in force the powers contained in their Provisional Order within a period of 12 months.

Thermo-Electric Tension between Compressed and Uncompressed Mercury.—Dr. de Coudres, of Leipzig, is reported to have succeeded in detecting a thermo-electric tension between compressed and uncompressed mercury. The compression was produced either hydraulically or by means of its own weight acting through a column of mercury. It was found possible to determine with certainty the direction of the thermo-electric current, and to measure its intensity for given pressures and temperatures.

Physical Society.—In the discussion on Mr. Mather's recent Paper, at the Physical Society, "On the Shapes of Movable Coils used in Electrical Measuring Instruments" (*The Electrician*, April 11, p. 578), Mr. C. V. Boys observed that "He himself had found, while working at the radiomicrometer, that No. 1 was the most advantageous shape." We are desired to state that this remark was not intended to convey the idea that Mr. Boys had, previously to Mr. Mather, found by actual calculation that this particular shape was the best, but only that his investigations had led him to much the same result.

Obituary.—General Sir John Henry Lefroy, K.C.M.G., C.B., F.R.S., LL.D., who died on Friday evening last, at Lewarne, a few miles from Liskeard, entered the Royal Artillery in 1834, and was director of the Magnetical and Meteorological Observatory at St. Helena from 1840 to 1841, whence he moved to a similar position at Toronto in 1842. During the next year he made a magnetic survey of the interior of North America, from Montreal to the Arctic Circle, and was subsequently scientific adviser to the Duke of Newcastle at the War Office on subjects of artillery and inventions from 1854 to 1855.

Toronto.—The City of Toronto's contract with the Toronto Electric Light Company expires at the end of the present year, says the *Electrical, Mechanical, and Milling News* of that city. In view of this, a committee of aldermen has been appointed to secure information on the following points: "What is the best system of electric lighting now in use? What would be the cost of a plant, &c., required to furnish 1,000 arc lights on the overhead system? The cost of the underground system. Whether the same machinery can be used for a combined underground and overhead system? What success has attended the underground system?" The city professes to be seriously considering the advisability of purchasing and operating its own electric light plant.

The Imchenetzki Battery.—In this battery the exterior containing cell is of tinned iron, with a base of cast iron. The interior cell, open at the base, is of paraffined cardboard, and contains eight porous diaphragms. Melted paraffin wax is poured at the bottom of the first cell, and when this is cold the second is introduced. There are thus nine compartments perfectly insulated, of which four contain sulphite of soda with plates of zinc, and the other five are filled with chromic acid with electrodes of specially prepared compressed graphite. In certain types both electrodes are of graphite. The E.M.F. of this battery is 2·12 volts, or 0·8 volt if both electrodes are of graphite. The battery, when short-circuited, gives a very constant current for several hours.

Eastbourne.—At the last meeting of the Town Council, a letter was read from the Board of Trade with regard to the charges of the Electric Lighting Company, and stating that the price should be 8d. instead of 10d. per unit. After some discussion, Councillor Wenham moved, and Councillor Ford seconded, "That the Corporation saw no reason why the Board of Trade fixture of 8d. should not be accepted," and on a show of hands the Council decided to act as the Board of Trade advised. Alderman Wallis strongly objected to the vote thus suddenly taken, on the ground that no time had been allowed to the members of the Council to consider the

Digitized by Google

Board of Trade letter before expressing an opinion upon it. The vote really meant the death of the electric light in Eastbourne, and with it the prosperity of the town.

Interruption of Shetland Telegraphic Communication.—A serious interruption, says the *Glasgow Herald*, has occurred in the telegraphic communication between Lerwick and the north isles of Shetland, owing to the breaking of the cable between the islands. A direct cable was laid some time ago, but the section between Unst and Yell gave way about a month since, and messages have for some time back been conveyed across Bloomel Sound by boat. Now, however, it is believed that the Yell Sound cable has also broken, the result of which will be to entirely cut off the two islands. Even should the fears as to the latter cable be groundless, the fact of the Unst cable being broken is serious enough, as it leaves the whole island of Unst dependent on a boat service during the spring cod-fishing, one of the most important fisheries of the year.

The Halifax-Bermuda Cable.—In the House of Commons on Tuesday Sir E. Watkin asked the Postmaster-General what was the cause of the delay in laying the cable contracted for by Her Majesty's Government with a private company between Halifax, Nova Scotia, and Bermuda; and when might the public expect that the cable would be in operation. Mr. Raikes replied that under the power given to the Treasury by Section 4 of the contract with the International Cable Company the time allowed for laying the cable had been extended to Midsummer next, so as to avoid the risks attending any attempt to lay the cable during the winter months. He was not able to state the precise date when the cable would be available for traffic. No doubt the Company would do all in its power to complete it at the earliest date, because the subsidy did not become payable until the cable was in working order.

Electric Soldering.—The development of electric welding has naturally led to the invention of devices by which heat may be applied in a somewhat similar manner in other processes in the arts. Prof. Elihu Thomson has recently devised an apparatus by which the heating power of the current is utilised in the process of soldering the covers of tin cans. The apparatus consists merely of a converter, with its secondary terminating in a metal ring, the lower edge of which coincides with the line of solder about the edge of the lid of the can. In order to insulate the ring from the can, mica is interposed. The mica is protected from injury by being itself faced with a thin ring of metal. To operate the device the current is switched on until the ring is brought to the proper temperature. The tin can, which is carried by a weighted lever, is then pressed up against the heated conductor. While the process described relates to the soldering of cans, Prof. Thomson has applied the method in other processes where materials are united by the employment of heat to fuse the uniting material.

Weybridge.—A public meeting was held last week to determine the amount to be raised for street-lighting purposes during the coming year. Dr. Sealy, one of the lighting inspectors, said they estimated that they would require £260 for the next year for lighting; and a 2¼d. rate would produce £264. He claimed that the inspectors, in providing the electric light for the modest rate of 2d. in the pound, had achieved a good deal. The cost of putting the wires underground would be £200 per mile, exclusive of the lamp-posts, which would cost about 30s. each. They had something like six miles over which the lighting extended; and there were 18 lamp-posts per mile. The contractors had offered, if the parish constructed the necessary earthenware conduit, to put in the wires and remove the present poles and overhead wires without additional cost. It was purely a question for the ratepayers as to whether the underground system should be adopted. After some discussion an amendment that the rate be 2¼d. was proposed and carried. It was suggested, but the idea did not appear to meet with approbation, that a subscription list should be opened for placing the wires underground.

The Henry Gearing for Electric Car Motors.—Mr. J. C. Henry, one of the earlier workers in the electric motor field, has recently devised a means of connecting the electro-motor to the car wheels, admitting of the former running continuously in the same direction, irrespective of the direction or motion of the car. The motor is placed on the front platform of the car; and its armature, instead of its being connected directly to the car axle by chains or gears, acts on a pair of friction wheels mounted upon a movable collar, which drives an oblique axle, carrying on its lower end a gear wheel to engage the driving wheel mounted on the car axle. By a lever on the car platform either of the friction wheels can at will be engaged with the friction wheel on the armature spindle, and consequently the oblique shaft can be given a rotation in either direction without changing the direction of the rotation of the motor. The friction wheels used in practice are of wood, and are reported as giving a firm hold and excellent service. The experiments tried with this mechanism have been quite satisfactory in their character; but Mr. Henry is now at work improving and modifying it, and in his later arrangements the motor and the driving devices are placed below the floor of the car.

A Simple Storage Battery.—The following directions for making a simple storage battery is due to the *Journal of the Telegraph*. Get two half-round porous cups and a round glass jar large enough for the two porous cups to stand in upright. Get two plates of sheet lead one-sixteenth of an inch thick, wide enough to fit the half-round side of the porous cups and deep enough to come an inch or so above the top edge of the cups and jar. Solder a stout copper wire or a screw post to each lead plate at the top. Place the lead plates in the cups and fill the cups nearly full with a paste made of red lead mixed with a solution of sulphate of soda thin enough to run like a cement. The glass jar containing the two cups should be filled to within half an inch of top of cups with sulphuric acid and water, about one part of acid to eight parts of water. The plates should be marked so that, in charging, the currents may be sent in the right direction. The cell may be charged by attaching to a series of a dozen sulphate of copper cells for 24 hours, or from a dynamo. A wooden cover may be fitted to the glass jar, and evaporation of the fluid should be replenished by adding water. Two or more cells of this battery will work small motors, lamps, and induction coils, and if thoroughly charged will retain a large volume of electricity for a considerable time. After once being well charged, four to six cells of sulphate of copper battery will recharge it.

Copper.—About a year ago, says *The Statist*, the copper "corner" came to a disastrous end, and the copper trade has since resumed something like a normal course. The stock of copper is still very large in comparison with stocks before the "corner" was initiated; but, nevertheless, it is being steadily reduced, production falling off and consumption being stimulated, as a consequence of a low range of price. The copper corner began in October, 1887, when the stock in England and France and afloat from Chili and Australia stood at 49,176 tons. The deliveries previous to that date averaged about 8,000 tons per month, but during the first three months of the speculation they averaged about 12,000 tons, falling in January, 1888, to a little under 6,000 tons. From that time till the collapse of the speculation, in March, 1889, the deliveries in any single month never exceeded 6,212 tons, and in February, 1889, they only amounted to 1,397 tons. The average monthly delivery in 1888 was only 5,300 tons. Simultaneous with this small rate of consumption during the "corner" period, supplies became very large; and whereas in 1887 the monthly supplies only averaged about 7,500 tons, in 1888 they averaged nearly 10,500 tons. The consequence was that stocks rose rapidly, until in March, 1889, they reached the enormous chronicled total of 124,876 tons. This, of course, was irrespective of invisible supplies. The natural consequence of the great fall in prices which occurred last year, and the large amounts offered, have been two-fold—consumption has expanded, and production has diminished. The figures of the twelve months ended March 31, 1890, show that with a supply of about 9,000 tons per month, the deliveries—that is, the consumption—averaged 11,750 tons per month, and the stock has been reduced from 124,876 tons in March, 1889, to 91,938 tons in March, 1890. Although prices are so low compared with the exorbitant prices demanded during the "corner," yet they are £7 a ton higher than the prices current before the "corner," and are sufficiently high to yield a moderate profit to producers.

MAGNETISM IN IRON AND OTHER METALS.*—XIV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 568.*)

§ 64. **Magnetisation of Iron Rods of Various Lengths.**—The curves of Fig. 32 are selected from a group of experiments in which an annealed wire of soft wrought iron, originally 300 diameters long, was tested by the ballistic method, first in its full length and then after the length had been reduced successively to 200, 150, 100, 75, and 50 diameters by cutting off equal portions (in each case) from the ends. The central part of the length, through which the magnetic induction was measured, remained unchanged throughout the series. After each magnetisation the rod was reduced to a neutral state not by the process of reversals, but by taking advantage of the fact that a soft iron wire loses sensibly the whole of its residual magnetism when it is briskly tapped. Soft iron is extraordinarily sensitive to the effect of vibration; to tap it when the magnetic force is in action very greatly increases the permeability, and to tap it when the force is removed does away almost completely with its retentiveness. So sensitive is it that when the magnetic force is removed the lightest touch of the fingers suffices to destroy much of the residue, and after brisk tapping only one or two per cent. will in some cases be found to remain. The residual magnetism of soft iron is in fact very insecurely held. So long as the metal is left perfectly at rest it does not appear to suffer loss through the mere lapse of time; but any variation of temperature, or mechanical disturbance of whatever kind, reduces it with remarkable rapidity.

The three curves selected for reproduction in Fig. 32 refer to the cases where the length was 200, 100, and 50 times the diameter respectively. The abscissæ give the magnetising force exerted by the solenoid, not the true H, as affected by the ends of the specimen. To give some idea of the true H, the lines O A, O B, and O C have been drawn; these show the reactions which ellipsoids of 200, 100, and 50 diameter respectively would exert. By measuring the magnetic force from them instead of from O Y, we get an approximation to the true value of H. The approximation is a very fairly correct one for the rods of 200 and 100 diameters; the curves for them when, rectified by taking abscissæ from O A and O B respectively, agree well with one another, and with curves for longer rods or rings of the same material. The diagram shows well what has already been sufficiently explained—how it is that soft iron shows little retentiveness when tested in the form of a short rod, though it shows much when tested as a long rod or as a ring. The broken lines show the gradual reduction which the magnetism suffered as the magnetising force of the solenoid was reduced to zero. By producing them past the axis O Y to cut O X produced we find that the "coercive force" of the material was 1·9, as in the experiment of Fig. 31, § 63, which dealt with another specimen of the same annealed iron wire.*

§ 65. **Wrought-Iron Bar.**—Fig. 33 is copied from a Paper by Hopkinson,† and refers to a ballistic test of annealed wrought iron by the method of the yoke (§ 59). The magnetic force was raised to 240, then reversed and re-reversed; but in the figure

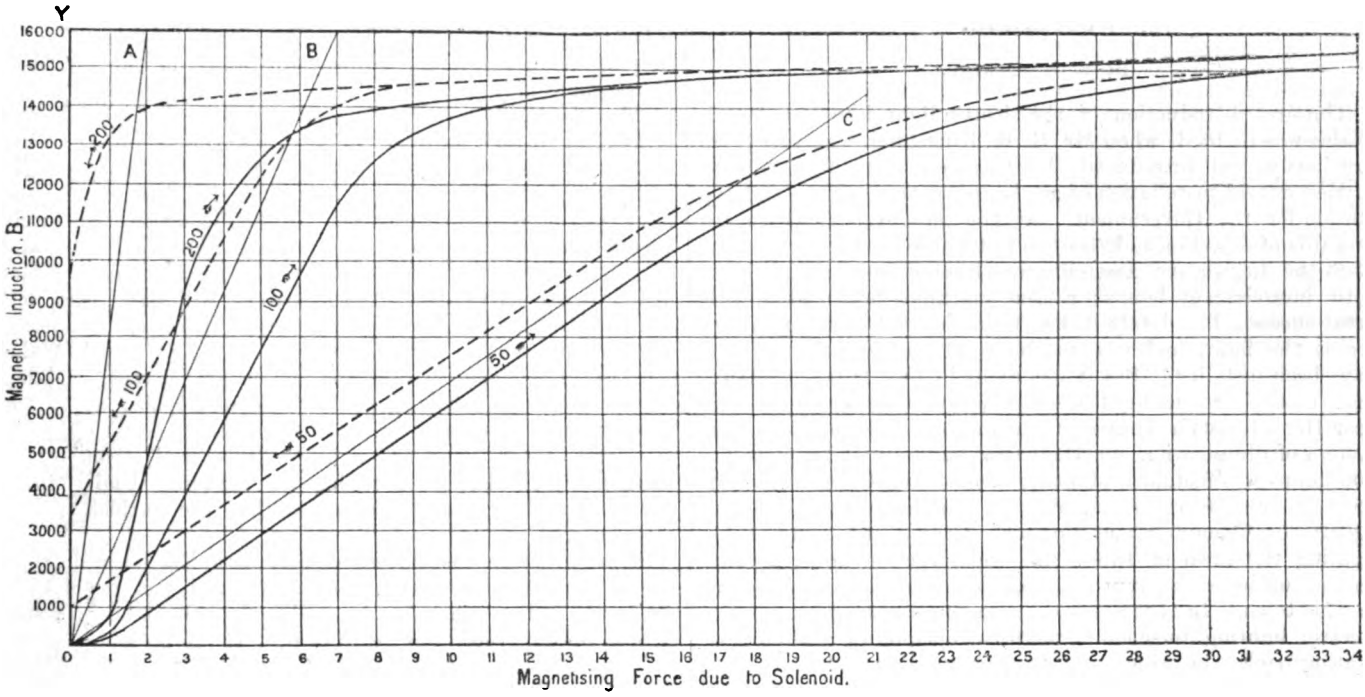

FIG. 32.—Magnetisation of Soft Iron Rods of various lengths.

the negative magnetisation and the parts relating to high forces are omitted. A comparison of this figure with those that have

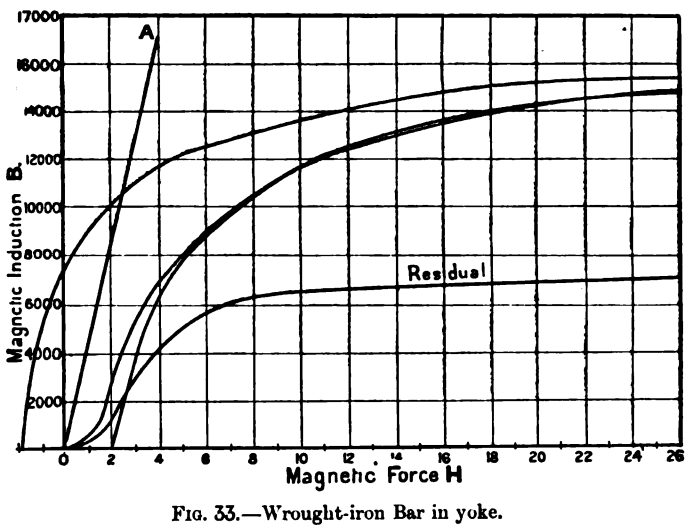

FIG. 33.—Wrought-iron Bar in yoke.

been already given suggests that the condition of endlessness was imperfectly realised (in great part, no doubt, through the

* All rights are reserved.

* In further illustration of the effects of length in the magnetisation of rods, see a Paper by A. Tanakadate, *Phil. Mag.*, November, 1888, where experiments are described dealing with a series of rods shorter than those referred to in the text.

† *Phil. Trans.*, 1885, plate XLVII.

Digitized by Google

action of the plane of section referred to in § 58), and that the curves might be approximately rectified by measuring H from a line such as O A (which has been added in copying the figure). This would make the bar within the yoke equivalent as regards endlessness to a bar (with free ends) about 150 diameters long. The coercive force in this sample has a value almost identical with the value found in soft iron wire, which strengthens the view that it is to imperfect endlessness, rather than to any specific difference in the quality of the iron, that one is to ascribe the comparatively small retentiveness of this bar.

(To be continued.)

THE PROGRESS OF THE ELECTRIC LIGHT IN AUSTRALIA.

BY E. J. ERSKINE.

The first introduction of the electric light into New South Wales was in 1881, when Mr. H. H. Kingsbury, who two years previously had introduced the telephone into this colony, carried out an installation of arc lamps at the Redfern railway station for the Government. At the present time there are upwards of 5,000 incandescent and 500 arcs in the colony. In 1883 the Legislative Assembly was lighted by the same firm with incandescent lamps; Edison machines were used with great success, but lately it has been deemed necessary to increase the light, and new machines of the Manchester type have been installed. But it was really in 1887 that the advantages of the electric light were properly recognised. In this year Her Majesty's Theatre Company decided to adopt this system of illumination for their new building, and a plant for 900 lamps was installed, Manchester machines being used. In 1888 Messrs. Harrison and Whiffen appeared in the field as agents for Crompton and Co., and secured the contract for lighting the town of Tamworth, where they installed a plant on the continuous-current system, which has given satisfaction in the town. In 1888, also, an impetus was given to the electric lighting business through the opening of a number of skating rinks, in which the proprietors desired to have the electric light; but as these installations were nearly all of a temporary nature, the work was not of a character to be encouraged, switches, cut-outs, ampere or volt meters being conspicuous by their absence. It would be more satisfactory to all parties concerned if the fire underwriters' rules were more stringently enforced; as although we have so far been very fortunate in Australia, having had no accidents that could be attributed to the electric light, it is more by good luck than good management; and now that the number of installations is increasing, it is most necessary that every precaution possible to prevent accidents should be taken.

Last year was a busy year in electrical circles in all the Colonies: in Melbourne on account of the extensions of central stations, and in New South Wales on account of the number of country boroughs who called for tenders; but perhaps the most important event of the year was the introduction into New South Wales of the first alternating-current transformer plant installed by Messrs. Kingsbury and Co. in Young. This plant is on the Thomson-Houston system, and the success has been such that the firm have received the contracts for Penrith and Lambton. It should, however, be mentioned that although this is the first introduction of the alternating-current in New South Wales, both the Thomson-Houston and Ganz and Co. have been working the system in Melbourne for some time with great success.

So far as motive power is concerned there appears to be a general leaning towards engines of the semi-portable type, and it is an exception when a plant is erected with separate boilers and engines. The standard of work done by firms in Sydney has been gradually improving during the last few years, and now it has reached a creditable pitch; the installations at the offices of the *Daily Telegraph*, and that in the new hotel in Bent-street—being the latest additions in Sydney—are in every respect highly satisfactory; also the temporary lighting of the Centennial Hall with arc lamps reflects great credit on the contractors. Perhaps the first thing that would strike an electrician coming here and going round the different installations would be the deplorable lack of ventilation and space in the engine and dynamo room, with one or two exceptions—a state of things highly detrimental to efficient working of the plant. Architects might be forgiven for not knowing that ventilation is a great advantage in dynamo-rooms from a commercial standpoint; but they should not lose sight of the fact that the attendant requires air to make it possible for him to look after his machinery. In one case the attendant is nearly suffocated by the fumes from some accumulators. It seems to be the general impression that any hole is good enough for electrical machinery.

Up to the present there is no central station lighting in Sydney; whereas in Melbourne there is a considerable amount of lighting done from the stations in operation, and there are other stations in contemplation. The reason for this difference in progress between the two largest cities in the Southern Hemisphere may perhaps be accounted for by the fact that in Sydney the Gas Company have a monopoly of the lighting; and although two Bills have at different times been introduced to enable companies to erect central stations and supply light and power, they have never got beyond the first stages, and have then been allowed to lapse. In Brisbane there has lately been a considerable movement towards the electric light; and central stations will, I think, shortly be an accomplished fact in the Northern Colony. If so, Sydney will have been left behind by all her neighbours, as at present there are no rumours of a central station here. However, the New South Wales country municipalities are, to a certain extent, making up for the indifference shown by the metropolis, as at the present time there are two of the interior towns lighted, in three others the work is in progress, and seven others are either considering or calling for tenders. Under these circumstances it must be admitted that the outlook is very promising.

So far as traction is concerned, very little has been done in any of the Colonies. Some time ago a trial was made of a car on the Julian principle; but, although the trial was successful, nothing more was heard of it. At the present moment an electric tramway is talked of for Balmain, a suburb of Sydney, and I believe it is to be on the Sprague system. Victoria once more takes the lead in the matter of electrical tramways, having one at Box Hill which is giving satisfaction; although I hear the rails through which the return is made are not all that could be desired, the joints being very primitive, and therefore the resistance very great.

There is one matter that is doing a considerable amount of damage to the electrical industry. I refer to the exaggerated reports that appear from time to time in the daily papers, copied from home papers, of the dangers of electric lighting in general and of overhead wires in particular. Many persons in the country districts reading these articles immediately imagine that the introduction of the electric light is nothing more or less than the introduction of a new kind of plague.

The subject, perhaps, most under consideration here at present in the country municipalities is, whether arc or incandescent lighting should be adopted for street lighting. The great argument relied on by the advocates of arc lighting is, that whereas it requires 500 horse-power to obtain 100,000 candle-power with incandescent lamps, the same number of candle-power would be obtained with 50 horse-power with arc lamps. Of course this is absurd; but they will not understand that the two systems cannot be compared by their nominal candle-power. So far, the five municipalities who have decided on the electric light have adopted the incandescent with good results, and it certainly hardly seems necessary in towns of 6,000 inhabitants to go to an enormous expense of lighting the town with arc lamps, the night traffic being quite insignificant.

In Victoria the railway authorities are turning their attention to the lighting their trains by electricity, and once more the younger colony will be ahead of New South Wales, as the system now in vogue here is an elaborate system of gas illumi-

Digitized by Google

nation, the installing of which involved a large outlay; and it is, therefore, not probable that the authorities will, for some time at any rate, consider the question of electric lighting, which would necessarily entail another large expenditure.

The prospects of electric lighting in the other Colonies, viz., New Zealand and Tasmania, should be very good, the abundance of water-power which is at the disposal of engineers giving every opportunity for the electric light to compete with any other system of illumination.

THE LIGHTING OF CHELMSFORD.

On Monday evening last the contract for the lighting of the streets of Chelmsford was commenced by Messrs. Crompton and Co. (Limited). The occasion appeared to be one of considerable interest and enthusiasm to the inhabitants of Chelmsford, as well as to the Mayor and Corporation of the town and those who were invited by Messrs. Crompton and Co. to witness the ceremony of inaugurating the lighting and to inspect the plant and lighting arrangements. On arriving at Chelmsford, the arrangement of the lamps and overhead wires in the streets was inspected by the visitors as they passed through the town on their way to Messrs. Crompton and Co.'s works. Mr. Crompton then conducted a number of those present over the extensive and ever-growing works of his Company, where a large dynamo, which has been constructed by Messrs. Crompton to the order of an American firm, attracted great attention. The machine has an output of 2,500 amperes and 60 volts when driven at 400 revolutions per minute. It is of the 4-pole drum-armature type, each convolution of the winding enveloping only one-quarter of the circumference of the core. The bars and end connections of the winding are joined together by means of iron set screws, and it is stated that in the event of a fault occurring the whole of the winding could be removed from the core within the space of an hour.

At about 7 p.m. the ceremony of switching on the lights for the first time under the contract was performed by Miss Brown, the daughter of the Mayor, and Mrs. Chancellor, the wife of the ex-Mayor of Chelmsford. At 7:30 p.m. a banquet to celebrate the event took place at the "Saracen's Head."

The generating plant is situated in Messrs. Crompton's Works, and consists of a vertical main driving engine, by Messrs. Marshall, Sons, and Co., which can be worked up to 150 horse-power. The stand-by engine is a horizontal one, by the same makers. The engines drive a main countershaft by means of rope gearing, the dynamos being driven from the countershafting by bands. The dynamos for the alternating currents are of the Mordey type, and those for the arc-lighting of the Crompton type. The alternator at present fixed is a 50 horse-power (37,500 watts) machine. The arc-light dynamo is capable of driving 20 lights in series of 2,000 candle-power each; it is separately excited, and runs at 900 revolutions per minute. 18 arcs are employed in the main thoroughfares, separated by distances varying between 50 and 110 yards. The lamps are of Messrs. Crompton's well-known type, and are carried on the top of wood or iron posts at a height of 25ft. from the ground. Clear globes are employed, and the effect is very satisfactory. The lighting of the less important streets, &c., is effected by means of 210 32 candle-power incandescent lamps, which are run in sets of 10 from converters. The lamps are arranged in lanterns of about 2ft. 6in. diameter; the roofs of which are curved and painted white, while the sides are of clear glass and slope inwards, formingan apex at the bottom. The lanterns are spaced from 40 to 70 yards apart; but as no opportunity occurred for forming an opinion as to the efficiency of the incandescent lighting, we must reserve our judgment until some future occasion.

The wires are carried almost entirely overhead, on posts erected at the edge of the curbstone. The cables are suspended from iron wires, which are supported by porcelain insulators. These are threaded upon a vertical bar carried by two brackets extending from the post. The arrangement has a decidedly neat and workmanlike appearance, and where there are two wires only, running straight down on one side of the street, the effect is certainly not displeasing. Where, however, the number of cables is greater and they branch out in several directions, the insulators and their supporting brackets being ranged at varying angles round the pole, there is no denying that the arrangement is somewhat unsightly. In the centre of the town, for a short distance, the cables are carried underground. The installation, altogether, does great credit to Messrs. Crompton and Co.; and we wish it every success.

SOME TESTS ON THE EFFICIENCY OF ALTERNATING-CURRENT APPARATUS.*

BY DR. LOUIS DUNCAN AND MR. W. F. C. HASSON.

Several Papers have appeared lately on the efficiency of alternating-current transformers, some of which have been of a more or less theoretical nature, while others have given the results of actual tests. I have never, however, seen any tests on alternating-current dynamos, excepting the experiments made by Dr. Hopkinson and Professor Adams on a de Meritens machine used for lighthouse work. Even the converter tests have given such varying results that one can hardly be certain as to the real efficiency. The introduction of the alternating system has been so rapid and is so rapidly increasing that people are apparently well enough pleased with the results not to bother about the smaller question of the reasons for them. But whatever the results may be, it is of value to know just where the losses in any system may come in, so that we may seek how to avoid them; if we are succeeding, it may enable us to increase the profits; if we are losing, it may help us to avoid further loss.

The apparatus, the measurement of which is the main subject of this Paper, consisted of a Westinghouse 750-light No. 1 dynamo, with a No. 2 exciter and an outfit of 40-light converters. This apparatus had been presented by the Westinghouse Electric Company to the Johns Hopkins University, and was tested a couple of months ago. The workmanship of the machines is excellent. The plant consisted of a 75 horse-power Armington and Sims engine driving the dynamo and exciter through a Tatham transmission dynamometer. Engine, dynamometer, and dynamos were firmly secured to heavy parallel timbers which served as a foundation. The converters were banked on a wooden framework at a distance of some 30 yards from the dynamo, and their primaries were permanently secured to the dynamo circuit, a switch in the latter serving to cut them off when desired. The ammeter belonging to the plant was put in this circuit and was read when efficiency measurements were being taken. The secondaries of the converters were taken to a switchboard and then to incandescent lamps mounted on racks.

Power Measurements.—The Armington and Sims engine supplying the power worked regularly and satisfactorily and the governor could be adjusted to give the speed required at the dynamo. The Tatham dynamometer was the one used for power measurements at the International Electriacl Exhibition held in Philadelphia in 1884, where its accuracy was checked by making with it a determination of the mechanical equivalent of heat. The result obtained in the latter measurement was 772·8 foot-pounds per degree Fahr., and shows that the dynamometer is practically accurate. A description of the experiments and of the instrument may be found in the report of the test made to the Franklin Institute, but it will not be out of place to briefly describe the apparatus here.

An endless belt, as shown in Fig. 1, passes over the driven pulley S, to the shaft of which the engine is belted, round the pulleys S_2 and B, to the driving pulley A, and back over B_1 and S_1 to S again. The bearings of the pulleys B and B_1 are in cradles pivoted on knife-edges, C, at their outer ends, and at the inner ends are connected by links at equal distances on the two sides of a knife edge which supports the scale beam, W. The outer side of the belt passes through the line of the knife edges, C, and therefore has no effect on the scale beam, but the tensions of the inner parts of the belt act directly on the scale beam, and as they are on opposite sides of the fulcrum they act against one another. The beam is so graduated that this difference of tension is read off directly in pounds, and this quantity—the difference of tension of the belt on the two sides of A—multiplied by its circumference and speed, gives the horse-power delivered. A weight travels on the beam W, and readings can be taken with great accuracy.

* A Paper read before the American Institute of Electrical Engineers March 18 1890.

Digitized by Google

Electrical Measurements.—The energy in the secondary circuit was measured by means of a Cardew voltmeter and a Thomson ampere-balance. As it is not the custom to put a number of secondaries in parallel, each converter had its separate lamp circuit.

Before making any efficiency test, the potential difference in the primary was regulated—there being a Cardew voltmeter in that circuit—and a separate measurement of the potential difference and current in each secondary circuit was made. When the test was actually in progress, the voltmeter and ampere-balance were used in one of the circuits, and the currents and potential differences in the others were calculated from the readings in this circuit together with the previous measurements. Both the voltmeter and ampere-balance were accurately calibrated, the former being checked after each test, while the latter had its constant determined with both continuous and alternating currents. The potential difference at the terminals of a non-inductive German-silver resistance in circuit with the balance was observed when a continuous current was flowing, and also with an alternating current of the same period as that employed in the test. The current in each case was calculated from the resistance and potential difference, and the results gave no appreciable difference in the constant for continuous and alternating currents.

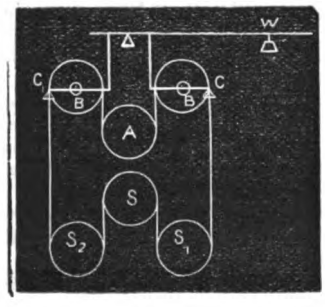

FIG. 1.

The following tables show at once the order in which the tests were carried out and the results:—

The efficiency of the converters was measured by placing them in a metal calorimeter, between the double walls of which water was allowed to flow. The temperatures of exit and entrance were observed, as well as the weight of water which passed through; at the same time the current and potential difference in the secondary circuit of the converter were measured. A separate observation gave the radiation, which was of course allowed for, although it was made as small as possible. A number of converters were experimented on, but I give but two of them, a 40-lighter, such as was used in the tests, and a 20-light converter which was very carefully tested by two of my students, Messrs. Bliss and McKeen. In the latter case the observations were made at slightly different potential differences, and the results show that the loss in the iron varies as we would expect it to vary, that is, very nearly as the square of the voltage. The variation will not be exact, as the losses due to the reversal of magnetism do not vary quite as fast as the square of the induction.

I would like here to call attention to the fact that in an excellent Paper read before this Institute, Prof. Ryan, of Cornell, found that the losses in the iron of a 10-light converter decreased greatly as the load increased. This was accounted for by the fact that there was a jar (evidenced by the singing of the converter) at the higher loads, due to the attractions of the secondary and primary coils. While it is true that the losses in the cores of very small converters are not exactly constant, yet they are nearly so, and a large part of the decrease found by Prof. Ryan is due to the voltage being greater at the low than at the high loads.

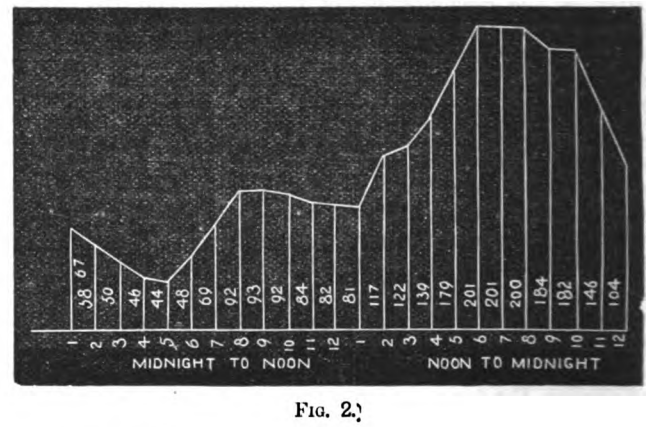

FIG. 2.

Looking now at the figures given in the tables, we are struck by two things: the very large amount of power absorbed in the core of the armature, and the very small loss in the converters on open circuit. The dynamo losses due to reversals of magnetism and eddy currents at the E.M.F. used in the test are no less than 6 horse-power, while the energy due to reversal of magnetism and eddy currents in the 16 converters is only 1·6 horse-power. Another rather striking thing is the almost constant ratio of primary and secondary currents over a considerable range. The maximum efficiency is about 78 per cent. It would seem that the losses could be divided into a constant part and one varying with the current; but this is not true with the older style and smaller converters of the Westinghouse Company.

Suppose we have a plant such as is described above, and use it for commercial lighting. Taking data from one of the local companies employed in supplying incandescent lights on this system, we have, for two 2,500-light dynamos, the following outfit of converters:—

Size of converters.	Capacity.	Number in use.	Total lamps.
No. 1	5 16 candle-power lamps	44	220
No. 2	10 „ „	61	610
No. 4	20 „ „	43	860
No. 6	30 „ „	49	1,470
No. 8	40 „ „	64	2,560
	Total lamp capacity		5,720
	Number of lamps supplied		4,557

Digitized by Google

I understand that the converters being added are of the larger sizes. The efficiency of the 30-light converters does not differ greatly from that of the 40-lighters. The accompanying Fig. 2 is a load diagram of this plant, selected from a number of diagrams as giving a fair average curve. If we have our dynamo working to its full capacity, then from the above data we would have a converter capacity of 23 40-light converters.

If, as in our test plant, these converters are 40-lighters, or 30-lighters—for the efficiency of these two sizes is about the same—we should have a mean loss in our plant of, say, 10 horse-power in our dynamos ($9{\cdot}6 + C^2 R$), and in the converters about 3 horse-power ($2{\cdot}3 + C^2 R$); or all together about 13 horse-power. From the above table we will have 750 lamps supplied, and taking the data from the load curve the average load would be in the neighbourhood of 1,300. This corresponds to about 20 horse-power, and the efficiency of the plant for 24 hours would be $\frac{20}{33} = 61$ per cent., minus the percentage of loss on the lines. This, in a properly installed system, should not average 2 per cent. so that the final efficiency would be 59 per cent. A continuous-current dynamo supplying the same outfit of lamps, with a maximum loss in the mains of, say, 15 per cent., would have a greater average efficiency. But I wish to point out that the maximum efficiency of the two plants would be about the same, so that they would require the same capacity of station outfit, boilers, engines, dynamos, &c. When more than one dynamo is provided, the efficiency is increased by using only one of them during the times of minimum supply, and always working, as far as possible, only a little below the maximum capacity of the machines.

Let us consider these results in view of the present condition of incandescent light distribution in the United States. I take it that what may be called domestic electric lighting is largely a matter of the future—it is certainly not a matter of the present. The majority—the great majority—of the lights in use are in shops, saloons, theatres, offices, &c. Most of the lights wired are in use at one time or another during the 24 hours, and the proportion of energy supplied to the total capacity of the lamps connected is much greater than it would be in the case of house lighting, where, on the average, only a small fraction of the possible lamp-hours are actually in use. Under these circumstances the scheme of alternate-current distribution is very different from what it will be when the attempt is made to supply an entire city with light, as they are attempting to supply London at the present time. If the object of the lighting company is to supply the demand that exists at present, then a system employing a number of small converters is preferable. Such a system is flexible and can be installed with a minimum expense for the more or less scattered demand which is presented in even the most closely-settled town. I take it that this is the great difference between the alternating and direct systems as at present installed in this country. The former skims over an extended district, taking advantage of its great flexibility to absorb any business which can be got; while the latter settles itself in a densely-built centre, instals a larger plant than is primarily demanded, and works up a business within the limits of economical distribution. Therefore, it is hardly right to compare the present systems of direct and alternating supply, as the latter has not been reduced to a point where entire districts are to be supplied.

To show the disadvantage of the present system for domestic supply, suppose we have an ordinary house such as one of us would live in; it would be necessary to have a converter of at least 20-light capacity. The constant loss is, say, 100 watts; so, leaving out the $C^2 R$ loss, we would have a total loss in 24 hours of $\frac{2400}{750}$, or about 3 horse-power hours, corresponding to, say, 45 lamp-hours. Taking my own experience, the actual number of lamp-hours used is about 30 lamp-hours during 24 hours, so the efficiency of the converter would be something like $\frac{30}{75} = 40$ per cent. It is evident that unless the losses in converters can be greatly decreased, a house-to-house distribution with a converter in each house would hardly pay.

It would seem, then, that if gas is to be really displaced, and serious competition with it is to be attempted, a different system of distribution must be worked out. We must replace the numerous small converters with one large converter supplying a comparatively extended district. If an extended secondary network is employed, some of the converters may be disconnected from the mains at the turn of minimum demand.

The authors then discuss how the increase in the capacity of converters will modify their design, and come to the conclusion that the efficiency of the larger converters will be greater than the smaller ones of the same design and working at the same temperature, but the output per pound of metal will be less. Referring, then, to Mr. Swinburne's British Association Paper on the "Design of Converters," the authors remark that they suppose most of those who have read it have been struck by the fact that almost all of the converter dimensions given by him are impracticable, either on account of the disproportionate heating of the larger sizes or the excessive fall of potential in the secondary. In increasing the size of dynamos we usually increase the output per pound weight, but there is the vital distinction between dynamos and converters that losses occur through the entire mass of the latter, and as we increase the volume we increase the losses in the same proportion. In the dynamo, on the contrary, there are practically no losses in the heaviest part of the apparatus, *i.e.*, the field-magnets. As a result, while we gain in efficiency in the larger sizes of converters, yet we must decrease either our induction or the rate of reversal, and the output per pound is not increased.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java Labuan Mosambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo, 5s., postage extra.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which is still further enlarged and improved (making 850 pages), is NOW READY. Orders should be forwarded at once to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.

LOCAL AUTHORITIES AND ELECTRIC LIGHTING ORDERS.

The Association of Municipal Corporations has undoubtedly scored a great triumph over the Board of Trade in procuring for Local Authorities that alteration of the "Model Order" which they have long been striving to bring about. In the earlier stages of the negotiations the Secretary of the Board was firm in his refusal to go beyond conceding the transfer of powers granted under the Order; but apparently, on an appeal to the President, the whole of the demands have been acceded to, a transfer of liabilities as well as powers being rendered permissible if the corporations in possession of the Order desire to part with these privileges. The immediate effect of this act of grace on the part of the Board is to still further accentuate the favourable position which Local Authorities hold in respect to electric lighting enterprise. But the ultimate effect will be far greater, and, to our thinking, will practically repeal some of the more important provisions of the Act itself on which the Board of Trade is supposed to be working. No doubt the Board is acting on competent legal advice in this matter; but if so, it only shows how elastic an Act of Parliament may be deemed to be when its precise stipulations are capable of being overridden or made nugatory by the Department which has to

Digitized by Google

administer it. The Local Authorities can now, it would appear, secure an Electric Lighting Order nominally for themselves and on the terms prescribed by the Acts of 1882 and 1888, but can immediately dispose of their acquisition on any terms they please to a private purchaser. In other words, all future electric lighting operations, wherever the Local Authorities have intervened, will be carried on, not under the Act of Parliament, but under the conditions imposed by an irresponsible intermediary.

We are left in no doubt as to the onerous character which these conditions will assume; for already, in a considerable number of cases, the consent of a Local Authority to waive its opposition to the granting of a Provisional Order has been given to private undertakers only after altering in every particular the terms and periods of purchase specifically laid down in the statute. It is certain that, in transferring the powers and liabilities obtained on their own application, the conditions of transfer will be not less advantageous to the Local Authorities. This, indeed, is the course recommended by the writer of the article headed "Local Authorities and Electric Lighting," in *The Times* of last Saturday, the concluding words of which invite them to "stipulate for terms of purchase at an earlier period than that allowed by the statute, and for conditions less ambiguous than those contained in the purchase clause of the Electric Lighting Act of 1888." By less ambiguous, the writer clearly means less profitable to the vendor; for, although there is some ambiguity in the language of corresponding Acts relating to tramway lines, there exists no doubt as to the meaning of the purchase clause in the Electric Lighting Act when read by the light of the debates which took place upon it, or, indeed, by the light of the words themselves, which exclude all idea of buying at anything but the then fair market value.

On the article just referred to, *The Times* had a leader of the same date, recapitulating the facts supplied by its well-informed correspondent, but declining to follow up his advice in the same confident and one-sided spirit. The operations of municipalities as commercial contractors are already carried on to an enormous extent, and are not always above the suspicion of abuse and jobbery. To extend these operations—as this latest concession in regard to Electric Lighting will greatly tend to do—cannot be contemplated with feelings of unmixed satisfaction. It is open to grave question, at least, as *The Times* points out, whether the functions of these municipal bodies should be so greatly enlarged, or that they should be allowed more and more to interfere in settling the terms of leases of profitable concerns with which they have no prescriptive right to meddle. There is nothing in the natural order of things requiring municipal bodies to become manufacturers and purveyors of commodities where private enterprise can do the business as well, or better; and certainly nothing to justify their being put in possession of advantages not enjoyed in ordinary commercial life. One of the most elementary stipulations attached to a statute conferring special privileges is that they shall not be bartered away immediately for a profitable consideration. Yet this is a condition which has been entirely waived in the case of Local Authorities possessing Electric Lighting Orders; and we should like to know the reason why. It may be possible to find a reason for municipal trading in the Socialistic teachings of the day; but it is straining Socialism very far when the law of the land is set aside or evaded in order to save the local community all the risks, and secure to it all the profits, of an enterprise which it has not the courage to take upon itself.

For this, in fact, is what we have come to if the writer in *The Times* has correctly interpreted the effect of the Board of Trade's arrangement with the Association of Municipal Corporations. They are not prepared to embark in the experiment of Electric Lighting on their own account for fear it should fail. But in case it should succeed in private hands—not otherwise—one of the conditions of the experiment is to be that the business shall then become the property of the Local Authority. It is a striking proof of the confidence that has grown up latterly in electric lighting industry that anybody can be found to accede to such unreasonable demands. But so it is; and we fear it is little use calling upon electric lighting undertakers to combine as a body for the purpose of making a stand in their own defence. The Local Authorities evidently count upon the competitive disunion of their clients, and *The Times'* correspondent confidently reckons on there being always plenty of applicants ready to take the rights and liabilities off the hands of the Local Authorities. We are told, therefore, that there will be another great rush for Provisional Orders, this time by municipalities who will dispose of them advantageously. It ought to be the business of electric lighting undertakers to see that this prediction is not fulfilled, and that the Local Authorities shall either assign the work to a private company on equitable terms, or be made to do it themselves. It is true they may transfer their liabilities to some one else; but not even the Board of Trade has yet ventured to say that their liabilities will cease if they cannot be transferred.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

ON SIGNALLING ACROSS RIVERS IN INDIA.*

BY W. F. MELHUISH.

Rivers which intercept lines of telegraph are crossed either by means of ordinary wires supported on masts of wood or iron, or by means of cables; and experience has not only shown that the former method is preferable, but also that the life of a river cable in India is a very precarious one. However, in the case of rivers of greater breadth than can be spanned, cables must be employed. The causes which affect river cables will be only briefly noted here; they are—

1. Deterioration of the shore ends by changes of temperature affecting the dielectric.
2. Damage from anchors of ships and steamers.
3. Alteration of the channels and cutting away of the banks.
4. Damage to the dielectric by lightning.
5. Imperfectly made joints.
6. Attacks by white ants and rats.

It not unfrequently happens that a river cable fails entirely, or becomes imperfect at a time when, owing to the force of the stream, a new cable cannot be immediately laid, or when there is no ready-made cable available, or when a considerable period must elapse before the new cable can reach the river. To provide for these contingencies, attempts have from time to time been made in India to signal across rivers without cables, and it may be of general interest to know what has been done in this respect by myself and others.

Three different methods appear to have been discussed and attempted, viz:—

1. Signalling through an imperfectly insulated wire.
2. Signalling through an ordinary bare wire.
3. Signalling without any metallic conductor.

More than thirty years ago, Mr. Van Rees, between Portsmouth and Gosport, in salt water, and subsequently Dr. Gintl in fresh water, tried to signal without a wire; but the result was in both cases a failure, and was supposed to be so because the resistance through the earth between the two groups of earth-plates on the same side of the river was too small as compared with the resistance between the two groups across the river. For success it was assumed to be necessary to bury the two groups of earth-plates on each bank from a quarter to a half-mile apart, and to connect them by thick insulated wire. In India, about the year 1858, Mr. Blissett acted on this plan, and obtained a fair measure of success by employing land lines of considerable length on either bank of the river. In the year 1876 the late Mr. Schwendler made some

* Paper read before the Institution on April 10, 1890.

Digitized by Google

experiments across the river Hooghly at Barrackpore, near Calcutta; and subsequently, during September, 1879, the late Mr. W. P. Johnston, electrician, made the following experiments :—

On the 9th September, 1879, he attempted to signal across a broad canal *without* any metallic conductor. Fig. 1 is a diagram of the connections, &c.

E = 10 Bunsen's cells joined in series ;

R, a needle instrument having a resistance of 1 ohm, also a bell telephone having a resistance of 4·25 ohms ;

W = a resistance of 1 ohm, e = four Minotto cells joined parallel } This arrangement exactly balanced the natural current through the receiving instrument.

A, B, C, D were copper-plates, 8ft. 8in. by 4ft. 4in. by 1-16th inch thick, buried on the banks of the canal. B was buried 15 yards distant from A, and D was buried the same distance from C.

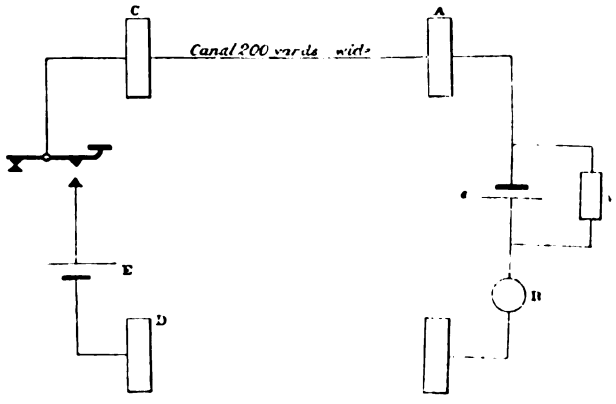

Fig. 1.

All the plates were buried parallel to the canal. The resistance between A and B was 7·5 ohms, and that between C and D was the same. Under these conditions both the needle instrument and the telephone (used, of course, as a telegraph, and not as a speaking instrument) gave distinct and readable signals.

After several days of experiment with the second method (Fig. 2), using a single bare 600lb. per mile galvanised wire, the following results were obtained :—

E = 15 Bunsen's cells in series ;

R, a polarised Siemens relay of 21 ohms resistance ;

e = 4 Minottos joined parallel
W = 10 ohms } Balanced the natural current.

The measured resistance of the circuit was + 2 – 20 ohms. The signals received were quite regular and safe ; the tongue of a relay worked an ordinary sounder in local circuit, and no difficulty was experienced in balancing the natural current through the relay. To balance this natural current is a most important element of success in this mode of telegraphing.

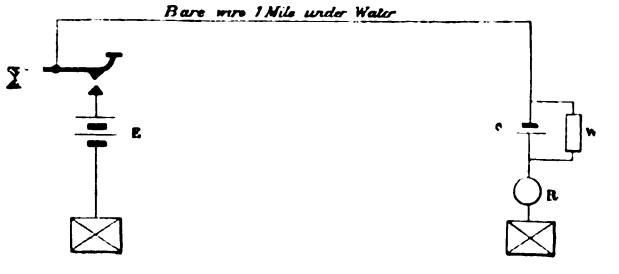

Fig. 2.

Subsequently three miles of the same wire were laid along the canal, the wire having previously been passed through a mixture of pitch and tar, and for the hour the instruments were in circuit perfect signals were received.

The experiment with the bare wire for a distance of one and a-half miles was not successful ; and as it appeared that in order to obtain signals the battery power would have to be increased as the square of the distance, the limit through which signals can be received on bare wire under water is very soon reached.

During May, June, and July of the year 1888, Mr. Johnston made a long series of trials across the canal and the river Hooghly, and the subsequent measurements and experiments led him to come to the following conclusions, viz. :—

That up to 1½ miles it is perfectly easy and practicable to signal through a bare wire under water.

That for greater distances, judging from experiments, it is not possible to signal in this manner.

In April, 1889, Mr. W. P. Johnston died, and the duties of electrician were entrusted to me. Having studied the recorded labours of my predecessor, and learnt that by pursuing the same lines it was hopeless to expect to be able to signal through a bare wire across a river that had a greater breadth than one and a-half miles, I resolved to change the class of signalling apparatus and to continue the experiment. Discarding continuous steady currents and polarised receiving relays, I adopted Cardew's vibrating sounder, and the sequel will show how completely successful the change of instruments proved to be. I began from the beginning, and tried to signal across a water-way without a metallic conductor by laying down two earth-plates on each of its opposite banks. Readable signals having been exchanged, the distance separating each pair of plates was varied, with the view of ascertaining how close the plates might be brought together, the signals remaining still readable. Readable signals were exchanged when the distance separating the plates was equal to the breadth of the river, reading becoming more difficult as the plates were made to approach each other, and clearer and more distinct as the distance between the plates was made to exceed the breadth of the river. I learnt from these experiments that in order to obtain signals of sufficient distinctness for the practical purpose of transmitting messages, it would be necessary to construct a line on each bank of a river much longer than the breadth of the river ; and as the rivers along the coasts in India are extremely wide, I became impressed with the impracticable character of such an undertaking, and decided to strike out a new line. This new line was the laying of two bare uninsulated iron wires across the water-way parallel to each other, and separated by a certain distance, the ends on each bank being looped together by means of an insulated conductor. Hence, though

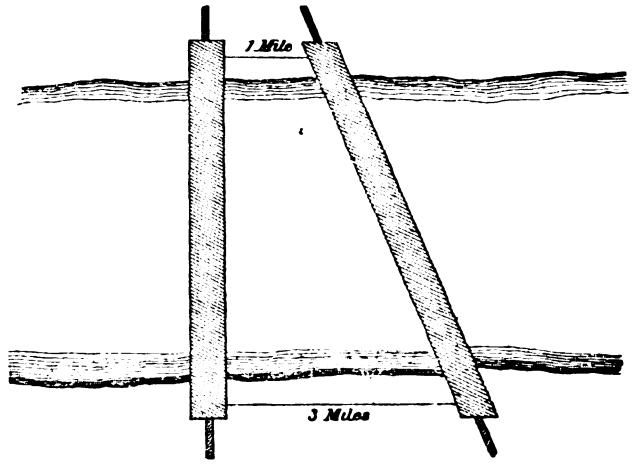

Fig. 3.

much of the circuit was laid under water, it was nevertheless a continuous metallic circuit. Beginning first with a complete square, by laying the wires as many yards apart as the river was wide signals were instantly exchanged that were incomparably louder than those that were exchanged when the same area was bounded by four earth-plates. The length of each of the two wires under water was next gradually increased to 740 yards, and the distance separating them gradually diminished to 35 yards, the strength of the signals diminishing proportionately, and ceasing to be readable when the wires were further prolonged. The conclusion arrived at from these experiments was that, for the practical and useful purpose of signalling messages across a broad river, in the absence of an insulated cable a complete metallic circuit was at least desirable. Acting on this conclusion, it was sought to apply it practically, and the following experiment was carried out :—At a distance of 15 miles west of Calcutta a cable is laid across the river Hooghly, which at this point is 900 yards wide. The iron guards of this cable were employed to form one of the metallic conductors, and at a distance of 450 yards down stream a single wire, weighing 900lb. per mile, was laid across the river to form the second metallic conductor, insulated land lines having been run up to loop the two parallel conductors together. The experiment was quite a success, the signals being readable without difficulty.

An experiment was next made on a defective cable across Channel Creek, at the mouth of the river Hooghly. This creek is crossed by two cables laid in the same trench ; the length of each is 3,000 yards, and one of them had been completely parted by a steamer's anchor. Several attempts were made to signal across by using the guards of one of the cables as a lead, and the guards of the other as a

Digitized by Google

return wire, but the efforts proved unsuccessful owing to the too close proximity of the cables. For every cable crossing there is a certain minimum distance apart at which the cables must be laid, and if this minimum, which depends on the breadth of the river, be exceeded, an absolute short-circuit becomes established. But although it was not possible here to signal through the iron guards, the most perfect signals were passed through the two conductors when they were formed into a loop, notwithstanding the fact that the two ends of the broken conductor were exposed in the sea and were lying at a considerable distance apart. An experiment was now made in order to ascertain what chance there might be in the future of signalling across the two conductors, should an accident occur to the good cable. Accordingly the conductor of the good cable was disconnected in the cable-house from the signalling apparatus and placed upon the ground, when the signals, though greatly diminished in volume, still continued to be distinctly readable. It may, therefore, be reasonably inferred that should the good cable suffer a similar fate to that of the defective cable, communication can, by means of Cardew's sounders, be kept up by looping the ruptured conductors until arrangements can be made for laying a new cable or repairing the defective ones.

It will probably suffice if from the succeeding experiments that were made to test the efficiency of the vibrating sounder in the case of conductors breaking down at river crossings I select the following three, exhibiting as they do progressive evidence of the value of this signalling instrument, and culminating in establishing it beyond dispute as one that can be relied on for carrying on independent communication through the iron guards of cables while the insulated copper conductors form parts of other circuits.

Experiment No. 1.—The local line from the Central Office, Calcutta, to Garden Reach is about four miles in length, and at about midway the wire spans a small river. Vibrating sounders having been put in circuit at each end of this line, the wire where it crosses the river was taken down and laid along the bed of the water-way. Signals were loud and clear at both ends.

From the success of this experiment it may be inferred that on any ordinary line, should the wire from accidental causes come off the insulator and make earth by touching the bracket, standard, or ground, or should the wire break and both ends of it be lying on the ground or in a water-course, communication could still be maintained by means of the vibrating sounders.

Experiment No. 2.—The line wire which connects the town of Chandernagore with Barrackpore is about 10½ miles long, 900 yards of which consists of a cable laid across the river Hooghly. Vibrating sounders having been joined up in the telegraph offices at Barrackpore and Chandernagore, the insulated conductor of the cable was thrown out of circuit, and the line wire on each side of the river was joined to the iron guards of the cable; thus for a length of half a mile out of 10½ miles the conductor was wholly under water, yet it was found quite feasible to transmit messages between the two offices.

From the success of this experiment it may be reasonably inferred that in the case of certain cable crossings, where the rivers are not too wide, should the copper conductor of the cable make dead earth or become insulated by parting, communication could still be kept up between the two offices on either side.

Experiment No. 3.—The terminus of the Northern Bengal State Railway at Sara is separated from that of the Eastern Bengal State Railway at Damukdia by the river Ganges. The opposite banks of the river in this locality are connected by two independent cable crossings. The length of one of these crossings is 1 mile 610 yards, and of the other 4 miles. The distance which separates the two cable houses on the Damukdia side is 3 miles 1,584 yards, and on the Sara side the cable houses are only 1 mile 211 yards apart, giving a mean lateral distance in alignment of 2 miles 880 yards. The two cable houses on each bank of the river have an insulated connecting land line. The two cable crossings and the connecting land lines form an irregular metallic circuit somewhat resembling that given in Fig. 3.

The connecting land lines having been joined to the iron guards of the cables, two vibrating sounders were placed in circuit, one on each side of the river, when signals so strong were transmitted across that it was not difficult to read them at a distance of 6ft. away from the receiving telephone.

From the marked success of this experiment it may be inferred that at all river cable crossings where the cables are laid in separate alignments (and the farther apart the better), should the cables become interrupted, communication may still be maintained from bank to bank by using vibrating sounders, thus avoiding the delay, inconvenience, and cost of a boat service.

It should also be remembered in the case of such a parallel cable crossing, that besides the circuits afforded by the copper conductors, when these are in working order, there is always an additional local circuit available by means of the iron guards between the opposite cable houses, and that this circuit could be used by means of the vibrating sounder as a talking circuit, in cases of necessity, without interrupting through working on either of the cables.

Each of these three experiments may properly be described as a delicate experiment. With so much of the conductor under water, the quantity of current which reaches the receiving telephone is so infinitesimal that signals could not be successfully transmitted if the vibrator were joined up in the ordinary manner. It is desirable in circumstances similar to these to reduce all the resistance external to the actual connecting lines to as small a quantity as possible, and therefore, when messages are being transmitted, the telephone at the sending end should be removed from the circuit, as also should the vibrator from the receiving end. To effect this twofold purpose a special form of signalling key (designed by the writer) is requisite, and should be used. The action of this key, together with the complete set of connections for a parallel cable crossing, is shown in Fig. 4.

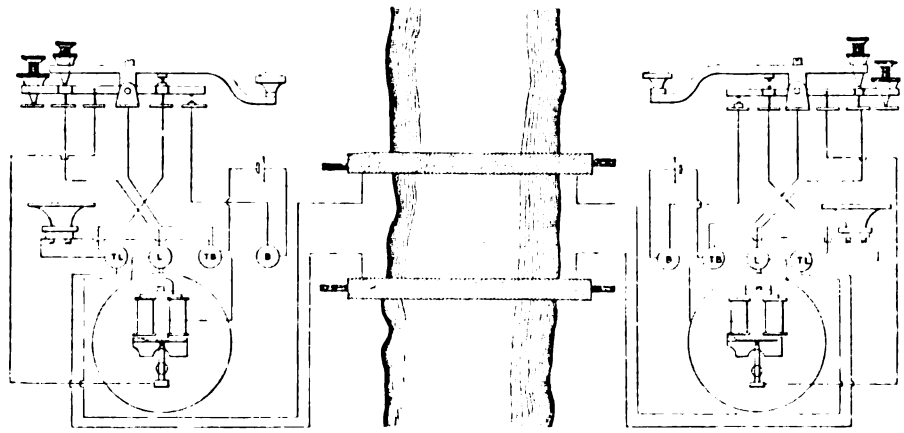

Fig. 4.

DISCUSSION (Authorised Abstract).

Major CARDEW said he was glad to hear that his vibrating sounder had been so serviceable in the experiments described in the Paper. He did not consider himself entitled to much credit for his sounder, as similar instruments had been used by others before him; it was rather the system he described before the Society in 1886 that was of importance. This system had been found extremely useful in cases of emergency such as occurred when the last heavy snowstorm broke down nearly all the wires in the metropolis. The idea of obtaining communication by bare wires as mentioned by Mr. Melhuish's Paper seemed to him good, and he thought copper wires would be better than iron ones. In addition to the armour of cables being used as a local talking circuit, it was easy, he said, by using the vibrator, telephone, and small condensers, to talk along the main conductor without interfering with the through traffic. Referring to the special signalling key shown in Fig. 4, he said that in his 1886 Paper he had given an arrangement for producing the same effect in what he considered a more practical way.

General WEBBER considered the questions dealt with in the Paper of considerable importance in practical telegraphy. The life of river cables in India was, he said, very uncertain, due in some measure to the great variations of depth which the rivers undergo; in some cases the depth changes from five to sixty feet in a single season. It must not be supposed, however, that cables could not be used successfully in rivers, for during the Franco-German War a six-wire cable was laid from Bromley to London

Digitized by Google

along the bed of a small stream in order to complete the communication with France *viâ* Beachy Head. This worked satisfactorily for six months. Another instance occurred at Wady Halfa, in the Soudan, where a piece of ordinary field line was laid across the Nile and served to transmit messages until an armoured cable was obtained. This latter cable was very successful. Referring to the use of Cardew's sounders for signalling without wires, he said the idea was not new, for they were employed some years ago in signalling across the Solent between Hurst Castle and Yarmouth. It was also found possible to communicate between Portsmouth and Newport, a distance of about 35 miles, *viâ* Hurst Castle and Yarmouth, although no metallic circuit existed between the two latter places, which are six or seven miles apart. The vibrator and telephone were also found very useful in Egypt for signalling through a badly insulated-wire to a lineman who had gone to search for the fault.

Mr. CHARLES BRIGHT said the utility and importance of Mr. Melhuish's experiments were not confined to communicating across rivers, but had a direct bearing on the difficulties existing in signalling between lightships and the shore. Mr. Willoughby Smith, he understood, had been successful in signalling to boats without communicating wires (*The Electrician*, November 2, 1888, p. 833), but Mr. Melhuish seemed to have failed in similar experiments. He was not aware whether Mr. Smith's experiments had been proceeded with.

Mr. GRANVILLE, referring to the method of signalling across rivers by uninsulated cables and insulated land lines, said he had recently found a patent, dated 1838, in which the method was described, and he believed it was tried between England and Ireland, but without success. Mr. Willoughby Smith's experiments were quite satisfactory, and they had been discontinued partly because the Telegraph Construction and Maintenance Company had overcome the difficulties in signalling to lightships in another way, and partly owing to Mr. Smith's ill-health.

Mr. WYLES was not surprised at the success which had attended Mr. Melhuish's experiments with Cardew's vibrating sounders. Some years ago, when he was working with them, the question was not what you could work through, but what you could not work through. Major Cardew's key was, in his opinion, simpler than the one devised by Mr. Melhuish.

Mr. MORDEY said Mr. Preece had informed him that the dynamos at Deptford affected the telephones in Paris. If this were so, signalling across seas was already accomplished.

THE DIATHERMANCY OF AIR IN RELATION TO THE EFFICIENCY OF INCANDESCENT LAMPS.*

BY F. HIGGINS.

It is occasionally useful to know something of thu state of the vacuum in incandescent lamps without injuring them by perforating the bulb with electric discharges. The property which air possesses of transmitting radiant heat in proportion to its density, affords a means for obtaining this information. I have not seen any mention of this property in works on the subject which I have consulted, and do not know whether my results agree with others which may have been obtained.

In order to make some comparative tests, I obtained, through the kindness of Major Flood Page, a number of lamp-bulbs fitted with similar filaments of platinum iridium, as nearly as possible alike in length. Some of these bulbs were exhausted to the highest possible degree, some left open to the air, and others exhausted to a pressure equal to 1-10th inch of mercury. With a sensitive thermoscope the different qualifications of the three descriptions can be made apparent. The lamps of each class being very similar in their behaviour, it is only necessary to give the results obtained with one of each type. The highest possible exhaustion is that which is supposed to be the condition of the electric lighting bulbs; the 1-10th inch gives a vacuum like that necessary for the Geissler tubes; the air-bulb, as before mentioned, open to the air.

By means of adjustable resistances and batteries, the three lamps were brought to the same degree of red heat, as nearly as could be judged. The potential at the filament terminals and the volume of current flowing were measured in each case, with the result that the air-bulb required, to produce the red heat, 7·02 watts; the 1-10th inch vacuum, 5·336 watts; and the highest possible, 0·646 watts only. With the same lamps in series the highest possible becomes white hot with a current which scarcely causes visible redness in the air-bulb filament, and only dull redness in the 1-10th inch vacuum. The relative conductibility of the three bulbs, as measured by radiation upon a sensitive thermoscope, was—

Air, 325°.
1-10th inch vacuum, 250°.
Highest possible, 35°.

When the same filaments were raised to incandescence, that in the air-bulb required 31·2 watts per candle; the 1-10th vacuum, 15·20 watts per candle; and the highest possible vacuum, 4 watts only per candle.

These results show that of two similar lamps, one, merely from imperfect vacuum, may require double the current that is necessary in the other to produce the same amount of light, and at the same time become dangerously hot. The two extremes of my scale show, for example, the absorption of nearly eight times the force in the case of the air-bulb that is necessary to produce the same effect in the most efficient lamp with a higher vacuum. It is possible that vacua produced by chemical absorption of carbonic gas may be more perfect even than this, and advantageous to use. There is always some air left in a vacuum produced by a pump; but it is possible to imagine that no gas will be left unabsorbed in the case of caustic potash and carbonic acid gas being employed. Lamps which differ much in the state of their surrounding medium differ also in their behaviour when current is applied. Those which have a very perfect vacuum attain incandescence slowly, and lose it in the same way; while those which are imperfect start suddenly into incandescence, and as suddenly lose it.

* Paper read before the Institution, April 10, 1890.

DISCUSSION (AUTHORISED ABSTRACT).

General WEBBER asked Mr. Higgins if he proposed any means of testing the degree of exhaustion without using the methods ordinarily employed by lamp makers.

Major CARDEW inquired whether he had repeated his experiments with lamps having carbon filaments.

Mr. G. S. RAMM asked if his apparatus would indicate the difference between a vacuum of $\frac{1}{5}$mm. and the most perfect obtainable. In his (Mr. Ramm's) opinion there was a great need of something to replace the ordinary coil test, which in the case of carbon lamps was unreliable.

Mr. GRANVILLE wished to know whether the thickness of the bulb made any difference in the efficiency, for he thought the heat-conducting power of the glass must affect the temperature of the filament. He also asked if it would not be advisable to use double bulbs, so as to have the benefit of the diathermancy of both.

The PRESIDENT said the well-known method of testing the state of the vacuum by feeling at the bulb whilst the lamp is alight was a fairly good guide. He thought the differences observed by the author were not due to diathermancy, but rather to connection and diffusion.

Mr. HIGGINS, replying to General Webber, said his apparatus had been used practically. In one case he received a lamp which was supposed to be exhausted to $\frac{1}{10}$in., but his thermoscope indicated a lower vacuum. On returning the lamp to the maker his prediction was verified. His apparatus was so sensitive that it gave a deflection of 600 divisions if touched with the finger. In answer to Major Cardew, he said he had found the radiation from filaments of different materials to be alike. Referring to Mr. Granville's question, he said he had not tried the effect of different thicknesses of glass, but he believed it better to use large bulbs rather than small ones. As to the cause of the phenomena observed, he once suspected that convection was operative, but after investigating the matter had concluded that it had no effect.

ON ELECTRIC MOTORS IN GENERAL RAILWAY WORK.*

BY DR. LOUIS BELL.

(Concluded from page 577.)

I have been considering up to the present the sort of railroad work most unfavourable to electricity—that is, general work over long distances. There are, however, certain cases in which, even now, electricity could be employed to great advantage. For example, take railway lines between neighbouring cities, where the passenger traffic is large and frequent trains are run. If there were two competing roads, one operated by electricity and the other by steam, I should expect at least 50 per cent. more travel on the electric road, by reason of its freedom from dirt and smoke and attendant inconveniences. The same, I think, would be true in the case of very many suburban roads, and in those cases where the distances are comparatively short, I should expect lessened running expenses by the use of electricity. More especially would this be true if electric braking should ever be put into successful use. Up to the present, however, it has been one of the things very beautiful in theory and attractive in experiment, but which no one has cared to attempt employing.

The case, however, where an electric system would work to the very best advantage is the elevated railroad. In such a case we have a compact system which could be supplied from a single power station in the most direct and economical way. The damage to neighbouring property would be enormously lessened, and the present objections to an elevated system would be in a great measure removed. Of the success and economy of an elevated electric system there can be no reasonable doubt, and I would go so far as to say that, in view of what can be accomplished by electricity, there is no reasonable excuse for permitting the use of ordinary locomotives on an elevated system. The question has never been properly agitated; but if it were, I can see but one possible result. The difficulties of running an elevated system by electricity are immensely less than those encountered in the opera-

* Read before the Chicago Electric Club, March 17, 1890.

Digitized by Google

tion of a great street-car system, like that in Boston. In particular, the bugaboo of electric-railroad men—repairs, would dwindle into insignificance; for lifted from the dirt and mud of the street, an electric motor can readily be given such care as would reduce the repairs to a comparatively small figure.

Let us look into the gain that could be made by using electricity on an elevated line. It is, I think, a peculiarly favourable case, and we, fortunately, have the facts and figures at hand to determine its probable advantages. I will put aside for the moment everything except considerations of economy and running expenses, and I will turn to the New York elevated system for our facts. The locomotives on the Manhattan railroad work under conditions anything but favourable to economy. They are on duty 20 hours per day, and of that time steam is admitted into the cylinder but six hours. The full horse-power of the engine is 185, the mean horse-power is said to be 70·3; as a natural result of this the coal consumption is high, being 6·2lbs. per horse-power hour. Now, let us count the cost of fuel for each engine, and we have an average consumption of 435lbs of coal per hour. What coal consumption will be required to furnish 70·3 mechanical horse-power on an electric system of distribution? In the first place, we shall have the advantage of being able to use triple-expansion condensing engines and the corresponding coal consumption is about two pounds per horse-power-hour. This would mean something like 15lb. of water, certainly a reasonable figure. I shall allow 125 indicated horse-power to furnish the 70·3 horse-power required. This certainly is a liberal estimate, meaning as it does an efficiency of only 56 per cent. from engine to car. This allows 90 per cent. efficiency for the dynamos, 90 per cent. efficiency for line, and a little less than 70 per cent. commercial efficiency for the motors. This estimate is surely within safe limits, for if 90 per cent. is high for the line, surely 70 per cent. is low for the large motors, for at least this figure can be secured with a good street-car motor. Against, then, 435lb. per hour of coal required for the locomotive, we have 250lb. of coal per hour required to furnish the same power to the train electrically; and besides, the coal required for the locomotive is of a higher grade than that which would be used with a stationary engine; for it has been found best on these small locomotives to use a rather high grade of coal, whereas I have estimated the coal consumption for the stationary engine on the basis of a cheap coal, having an evaporative power of 7 to 7·5lb. of water per lb. of coal, and costing less than $2 per ton in New York. Bearing in mind these figures, we see that the saving of fuel must be considerable. The coal for the New York elevated road costs over $700,000 per year. In view of the facts I have just set forth, I think, on a conservative estimate, there will be a saving of $400,000 per year by generating the power at the central station and distributing it electrically. This means lessening the operating expenses of the system by a very perceptible amount. Apart from the bare cost of fuel, the saving and handling of coal and ashes and furnishing water will be no small item. But even this great saving in operating expenses would not represent the saving which could be effected in operating a new elevated road by electricity. In the first place, the damage to adjoining property would be enormously lessened by avoiding the noise, smoke, and dirt of a locomotive. In fact, I believe that the saving in the cost of right of way would go far toward paying the expenses of equipping the road electrically. But this is not all. The use of locomotives makes necessary the use of larger train-units. Larger train-units mean, on the score of safety, running at rather less frequent intervals; and that in turn means giving up that as yet unrealised ideal of rapid transit, small trains running at such frequent intervals that it would never be worth while to run for one. With lighter trains, running at more frequent intervals, the strain on the supporting structure would be greatly lessened, and the load more uniformly distributed; consequently the whole structure would be made light in appearance and reality, costing considerably less and being far less unsightly than those now in use. Taking this into account, it seems very probable that an electric elevated railroad could be built and equipped at a less cost than if it were to be operated by steam. The great ease with which small train-units are handled on an electric system should of itself be the strongest possible recommendation.

The question naturally arises, how could we equip an electric elevated road to secure the best results? This opens a wide field for discussion, and I can only enter it to give you my own personal views on some points which might be of advantage. Personally, I do not believe in the single car as the unit of transportation: firstly, because it increases the cost of equipment enormously; and secondly, because in running at a high rate of speed it is inconvenient to run independent cars as close together as is necessary to secure proper accommodation. On the other hand, I do not believe in long and heavy trains. The necessary speed for the service being known, I think the best general result would be obtained by using as many small trains as could be conveniently operated at the required speed. By small trains I mean trains consisting of motor-car, and say, two or three light passenger coaches. I am a firm believer in a motor-car, rather than motors placed under each car, for the very practical reason that motor isolated and placed in a separate car can be given immensely better care than would ever be received by a motor hidden beneath an ordinary car. If we are to secure the minimum of repairs and the fewest possible number of break-downs, I think it must be done by giving the motors steady and careful attention; and I believe this end can best be reached by a separate motor-car, so constructed that the motors and all the running gear can be under constant inspection. I see no objection to a composite motor-car containing compartments for passengers, provided the above condition is fulfilled. As to electrical equipment, I think the problem is not particularly difficult. The size of the motor to be used must be regulated by the train-unit proposed. Perhaps, for the unit suggested, two 30 horse-power motors would answer as well as anything. It should be remembered that, isolated as the elevated track would be, it would be practicable and safe to use higher potentials than is customary in ordinary street-railroad practice.

The distributing conductors on an elevated system could be arranged in whatever way would prove most convenient, quite irrespective of the present limitations. Neither would the amount of copper required be at all prohibitory. For example, take ten miles of double track, with the power station somewhere near the middle point, the wiring would of course correspond with the number of trains to be run; but, working on a three-wire system, with track as balance circuit, the equivalent of two copper rods one inch in diameter would serve to handle a very large equipment, and still give a high efficiency for the line. The weight of this conductor would be about 16 tons per mile of double track, certainly not a prohibitory amount. By using two power stations, this amount of copper could be reduced to one-fourth. If the amount should still seem too large another interesting possibility appears. Would it not be possible to operate an automatic block system of series distribution? By dividing the double track into sections, and supplying these from one or more power stations, it would be possible to avoid most of the difficulties of series distribution, without sacrificing much in the way of line efficiency. We must remember in this connection that the principle of electric braking is easier to apply on such a system than it is on a system of distribution at a constant potential, as ordinarily practised. Electrical braking has not been put into operation in a commercial way, but some competent authorities have estimated that the saving from its use might be as great as 40 per cent. in power required. Such saving would be well worth effecting, even if it were less than the above amount, unless there should be good mechanical reasons to the contrary; and inasmuch as working upon the block system would do away with many of the objections to series traction, I think, to say the least, this line of operation is well worth careful investigation.

In a great city like this, rapid transit is becoming more and more a necessity, and now, before great investments have been made, is the time of all others to try to forecast the future, and see to it that the rapid transit given the city is the very best that modern enterprise can secure. The reform cannot long be delayed; it is only a question of who will be the first to display the necessary enterprise and energy, and give this city a system of rapid transit suited to its needs, and to the age in which we live!

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—TUESDAY, APRIL 15.

The Grievances of Telegraphists

Earl COMPTON moved: "That in the opinion of the House the present position of telegraphists in London and elsewhere is unsatisfactory, and their just grievances require redress." These grievances were of long standing, not only in the central office but in the provinces, and they extended also to Scotland and Ireland. Both males and females complained bitterly of the conditions under which they performed their work. That work had increased enormously since the introduction of the Fawcett scheme in 1881, and as the work had increased the grievances had increased also. Those grievances might be summarised under four heads—(1) the hours of duty; (2) the question of pay and salaries; (3) the question of classification and promotion; (4) the very burning question of meal-times. There was a complicated system of regular and irregular work and of overtime; and the principle upon which this was carried out seemed to be that of extracting the largest possible amount of work out of each individual at the least possible cost to the country. In the Fawcett scheme of 1881 it was laid down that as a rule there should be 16 hours' work for two days' work, and that was to be divided so as not to give more than 11 hours on any particular day. He contended that that scheme had not been adhered to. There had been weeks, particularly in the central office, when the hours of work had been 10 daily. That meant 20 hours in two days instead of 16 hours under the Fawcett scheme. It was said that this had been compensated in the succeeding week, when there were only 36 hours of work, or six hours a day. He maintained however, tha

Digitized by Google

was no compensation. This irregularity of hours was a great hardship to those who were working in the telegraph office. As regards overtime, he found that during the summer of 1889 for certainly a fortnight the telegraphists were worked something like 196 hours. That made 98 hours during a working week, including regular hours and overtime. He contended that those hours were too long for any public servant (hear, hear). He was unable to admit that the overtime work was completely voluntary. A man might volunteer for two or three hours' work, which, perhaps, might be extended to even 14 hours out of the 24. The men were called upon for overtime at a moment's notice, and one clerk was suspended for refusing to do overtime, though he pleaded ill-health as an excuse. As to annual leave, the telegraphists were asking for one calendar month's leave for those who had served 10 years, and three weeks' leave for those who had served less than 10 years. This demand was in accordance with what Mr. Fawcett had intended. The telegraphists had no Bank holidays, and worked on Sunday; and these facts ought to be taken into account. For his own part he wished that there were no Sunday labour; but, admitting that it was necessary for a certain number of telegrams to be sent on Sunday, Sunday labour should be limited as far as possible, and should be paid as full overtime. As to pay, the highest officials were, of course, well paid, and deserved to be. Since 1880 the pay of superintendents had risen from £300 to £400, while the pay of the assistant-superintendents had risen from £210 to £300. Before 1881 the maximum pay of the senior clerks was £160 a-year; now it was only £190, a rise quite disproportionate to that of the assistant-superintendents, who were next above the senior clerks. Moreover, senior clerks were in many cases doing the work of assistant-superintendents. The different classes of clerks had not increased in the same ratio, and they ought to be enlarged to permit of speedier promotion to the *maximum* of £190 a year. As it was, some clerks might secure their promotion in seven or eight years, while others might have to wait for 18 years, though all had equal qualifications and length of service. He hoped that something would be promised in connection with this matter of classification. Then there was the question of meal-times. There was at present no cessation of work for meals during the turns between 2 p.m. and 10 p.m., 3 p.m. and 11 p.m., 5 p.m. and 2 a.m., and 8 p.m. and 4 a.m. Sometimes, of course, the clerks might have spare moments, but very often their work was continuous. It would not be a satisfactory answer now to say that grievances were still under consideration; and he inferred from an answer given by the Postmaster-General last year that difficulties had not arisen from the interposition of the Treasury on financial grounds. He should like the House to be told whether there was any increase in the cost of the service through the passing of the Fawcett scheme, and whether the improvements promised under it had been carried out. If there were any deficit in the revenue from the telegraphs it was the fault of those who paid too high a price for them, and the telegraph clerks ought not to be made to suffer for that fault. The Treasury objected to the voting power of an organised agitation being brought to bear on the House of Commons, and threatened the suspension of promotion in any branch the members of which were henceforth known to adopt methods of extra-official agitation. He called it a monstrous doctrine that men were to be punished by taking from them the benefit of a scheme because they adopted what was called extra-official agitation (hear, hear). The action of the Postmaster-General in the Cardiff case proved that the right hon. gentleman concurred in the paragraph of the Treasury letter, and that made it necessary for the House to show that it did not object to men combining in a legal way, whether they were Civil servants or not. He asked that a speedy and reasonable remedy might be offered for these grievances. The duties of the operators were of a harassing character. Fifty per cent. of the telegraphists retired the victims of mental and nervous affections, brought on by bodily and mental fatigue. Juniors were expected to make progress in the knowledge of science and of delicate machinery, and seniors were expected to be scientists, linguists, and geographers. Cipher and code telegrams were enormously on the increase, and an error in a figure or word might be followed by the most serious consequences. The accuracy with which commercial and press telegrams were transmitted was well known to the public, who regarded telegraphists as a deserving body of public servants, to whom they would desire that justice should be done; and he had, therefore, pleasure and confidence in moving the resolution (cheers).

The motion was seconded by Baron F. J. de ROTHSCHILD.

Mr. RAIKES said that the noble lord had brought forward this subject at a time when the Government had not had an opportunity of arriving at any conclusion with regard to the proposal it embodied, while he had raised a number of small points of detail which were at the present moment occupying the attention of the Department. The noble lord had ranged the grievances of the telegraph clerks under four heads—namely, those which related to the hours of duty, to the rates of pay and allowances, to classification and promotion, and to the amount of leave. He complained that no official communication had been made to him with regard to the grievances of the London telegraph clerks before this motion was brought forward in that House, a course which he thought was altogether unprecedented (hear, hear). He could scarcely understand how the noble lord opposite, who had evidently taken up this subject most conscientiously, could have reconciled it with his duty to have brought forward this motion without having previously given the Department an opportunity of investigating the grievances which he alleged existed.

Earl COMPTON said that he certainly understood that a petition had been presented from the London telegraph clerks to the Postmaster-General on the subject. The petition, however, did not appear to bear a date.

Mr. RAIKES said that the only communication that he had received from the London Central Telegraph Office was a request made to him three days ago, some time after the noble lord gave notice of this motion, that he would receive a deputation which would present a memorial to him; in answer to which request he had directed a reply to be sent, appointing a day in the course of next week, when he hoped to receive that deputation, and to hear what those who composed it had to say (hear, hear). He was, of course, aware that there had been a petition flying about the country for some months past, which he had seen unofficially in the newspapers; but he might remark that the last persons to whom the grievances referred to in that petition were made known were the official superiors of the Department. The first petition on the subject that he had seen from the provincial offices had been one from Newcastle, which had been presented on February 28th in this year, and this had been followed by a great number of other petitions in identical terms from other offices. It was on March 4th, four days after that petition reached him, that he came to the conclusion that whilst it was not in his power to entertain or to recommend to the consideration of the Treasury several of the points that were raised by that document, yet that with regard to the other points he would take steps to secure their consideration by the immediate appointment of the best departmental committee he could select, upon which he would invite the Treasury to be represented, with the view of seeing how far the grievances complained of could be met (hear, hear) The Committee had only been sitting for a little more than a fortnight, and of course they had not yet been able to frame any report. He could assure the House that he had lost no time before endeavouring to probe to the bottom this question of alleged grievances. In the petition from Newcastle and in other provincial petitions which had reached him nine points were raised. With regard to four of these he should not be acting fairly by the men if he were to hold out any hope that their demands would be considered. In the first place, he could not encourage them to hope that the demand for the abolition of classification would be granted. Why should a cardinal principle of the Civil Service be modified in favour of one particular branch of the postal service? The abolition of classification in the telegraph service would entail an addition to expenditure in the service generally of £990,000 a year, for Mr. Fawcett having placed the telegraph service and the postal service on exactly the same footing, it would be impossible to improve the position of one branch and not to improve in a similar way the position of the other. The second demand which could not be entertained was the demand concerning the annual increment of the pay of junior officers. At present the increment was 1s. 6d. in the weekly wages, and the petitioners were anxious that it should be raised to 2s. Those who supported this demand needed to be reminded that these clerks had entered the service of the State on well-understood and recognised conditions (hear, hear). In their petitions they gravely stated that they were prevented from performing what they called "the duties of manhood" because their pay was so poor (laughter). What they meant was that they were not able to enter the state of matrimony eight or nine years before an ordinary member of the middle class would think of undertaking the burden of a family. Of course he should be very glad if all these deserving men, excellent servants of the State, were receiving much larger incomes. But the Government must consider what were the terms on which these telegraphists had entered the service of the State, and it was a little hard that they should be told that those terms, after they had been freely accepted, were inadequate and insufficient—nay, almost savage and barbarous in their results. They did not include the burning "dinner" question, which arose in London only; but he should be glad to consider whether he could include in the purview of the departmental committee any fresh point of that kind raised by the London memorialists as soon as he should have seen their petition. He would now tell the House what were the five points which he had referred to the departmental committee. The first was as to the sufficiency of present wages; the second was the request of the petitioners that all overtime should be paid for at the rate of one and a quarter; the third was the demand that all Sunday work should be paid for as overtime; the fourth was the demand that sorting clerks and telegraphists of ten years' or less service should receive three weeks' annual leave, and that those of more than ten years' service should have one month; and the fifth was the request that full pay should be allowed during absence from duty through sickness. He thought it extremely desirable, if possible, that he should be fortified with a unanimous report of the Committee before requesting the Treasury to take any action. He had decided, before these questions were raised in the agitated form in which they had recently been presented to the public, that there were three principal branches of the service which required special consideration. The most important were the superior officers of the Telegraph Department. The noble lord had referred to what he had heard from Liverpool that morning. Only a fortnight ago he obtained the sanction of the Treasury to a considerable improvement in the position of these officers at Liverpool. The consequence was that about 40 promotions had been made on the telegraph staff. Liverpool was the largest and most important centre; but it was intended to take Manchester, Birmingham, and other large towns in order. Although he had not been able to give any countenance to the proposal for the abolition of classification, which would in effect be the abolition of promotion by merit, it would be seen that he had not been slack in giving effect to the real requirements of the service, and that in advance of the demands made upon him. He sympathised with the case brought forward by the noble lord with regard to the hours of duty. But he was obliged, as the head of any department would be, to consider first the exigencies of the service. Reasonable care would, of course, be taken to prevent cases of hardship. It would be a scandal if the servants of the State were exposed to hardships which might easily be prevented. But, as everybody knew, the telegraph service was necessarily exposed to great fluctuations, in which occasional cases of hardship were inevitable. And he was sure that it would not be believed that the Department was indifferent to the hardships inflicted upon individuals (hear, hear). He could assure the noble lord that everything should be done which he could do to diminish any undue pressure (hear, hear). He had regarded the passage quoted from Mr. Fawcett's scheme as the recognised principle of the Department, that two days' work

Digitized by Google

should not exceed sixteen hours, and that no day should exceed eleven hours. The Secretary to the Treasury could bear witness to the importunity with which he had urged additions to the staff. But these questions were complicated by the considerations to which the noble lord had very fairly referred, viz., that the men who were complaining of overwork were not extremely in favour of additions to the force, because it diminished their opportunities of adding to their salaries by overtime. The noble lord would be surprised if he knew how great was the increase of the staff during the last few years. As regarded the dinner-hour in London, he did not see any great hardship if men whose hours were from two to ten were requested to dine before they came on duty. They were allowed time for refreshment between five and six, and it was enough if these men, who could hardly expect a life of luxury, were enabled to enjoy reasonable comfort. He admitted the exceptional character of the Submarine clerks, who had special claims on the consideration of the Department. They were handed over to the Government, which had but an imperfect knowledge of their position in their former employment. He had had the pleasure of meeting a deputation of these clerks, and had told them that though he could not promise the large gratuities to their widows which the companies had granted, yet he hoped to improve their position. The only other matter he could refer to was the circular issued from the Treasury under the Government of the right hon. member for Mid-Lothian. The responsibility for that circular rested with right hon. gentlemen opposite, and the quotation which had been made from it to-night was the first word he had ever heard of it. Whilst he thought that the language used in that minute was of rather too uncompromising and peremptory a character, he could not but think that it would be a bad thing for the Civil Service if its members were constantly to be bringing their grievances before Parliament. He hoped that, after the statement which he had been able to make that evening, the House would recognise the claim of every Government that the House would not interfere with matters of departmental administration except where they thought fit to censure the Minister in charge. So long as a Minister occupied his position at the head of a department, he ought to be allowed to conduct it in his own way. He ventured to hope that the House would leave questions of this sort in the hands of those who were directly and primarily responsible for them, in the belief that the grievances of the servants of any department were not likely to lack careful consideration, and, he believed, just and fair treatment. (Hear, hear.)

After some discussion, the House divided, when there voted—

For the motion	103
Against	142
Majority against	—39

The motion was therefore lost.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 3, 1890.

An Electrical Trust.—A rumour which is floating about at the present time, and finds expression in an indefinite way in the newspapers, is much talked of in electrical circles. It is to the effect that the equivalent of an Electrical Trust is about to be formed. The parties to the Trust are variously stated as the Edison and Thomson-Houston Companies, and the Edison, Westinghouse, and Thomson-Houston Companies. It is hard to tell whether the rumour has any real foundation, though the name of Henry Villard, of railroad fame, is prominently connected with the supposed enterprise, as he is known to be much interested in electrical affairs. The latest report is that the combination will include at present only the Thomson-Houston and Edison Companies, and that the Thomson-Houston stock will be watered before the combination. All this, of course, is entirely unofficial, as those prominently interested in the case in question refuse at present to say anything about it. In the case of such a combination it is said that the motor business would be turned over to the Thomson-Houston Company, while the Edison Company would retain the lighting business. It is suggested that the Westinghouse Company, if not included at first, may enter the trust later. Of course, all this is mere conjecture, and whether anything will come of it time only can tell. The three companies in question have control, directly or indirectly, of an enormous proportion of the electrical business of the United States, so that a direct combination, or a mutual understanding even, would practically mean an electrical trust to control prices and distribute the electrical business of the country among the principals of the trust. The thing which seems to cast the most doubt on the report is the fact that there have been no preliminary overtures between the companies, and up to the present time they have been on terms anything but friendly, while the competition between them has been of the sharpest character, so that anything like an amicable agreement would be like a thunderbolt out of a clear sky. However, a few days, or possibly weeks, will prove or disprove the truth of the rumour.

Electrical Execution.—Public attention to electrical execution seems to be just now undergoing a revival. For the past few months the agitation has been fortunately subsiding, and in electrical circles it was thought that the obnoxious execution law would be repealed, and that the whole matter would become ancient history. A decision, however, of the Court of Appeals in the case of the condemned murderer Kemmler was decisive as to the constitutionality of the law; consequently, there are now half-a-dozen murderers under sentence to die by electricity, and unless there should be a pressure brought upon the Governor to pardon one or all of them, there will be at least one electrical execution within the present month; consequently public interest is again aroused, and the daily press indulge in ghoulish reflections over the possibilities of this method of taking a man's life. The whole affair has been unfortunate from the beginning in its effect on electrical interests, and meanwhile the Courts have been made the arena for a vicious combat between various electrical interests. Possibly, after one or two condemned men have been executed according to the provision of the law, public interest will die out, but at present the agitation which has been stirred up is anything but agreeable to electricians.

Electric Traction.—Several new storage-battery cars are in process of construction, and it is interesting to note that there seems to be at present a reaction towards a single motor for a car, instead of two motors, independently geared to the two axles, according to the present practice. There is also marked interest in devices by which motors can be kept running at full speed irrespective of the rate or direction of motion of the car. Several clutches for effecting this result have been devised and are in various stages of progress, although none of them as yet have been given a trial on a practical scale.

Report of the State Senate Committee on Electric Lighting.—The Committee of the State Senate, which has been investigating electrical matters in this city, has at last succeeded in evolving a report which on the whole is very satisfactory to electricians; and, considering the vast amount and varied character of the evidence which was taken, so favourable a result is rather remarkable. The general decision is in the line of requiring underground construction in all cities having 125,000 inhabitants or more, but it is gratifying to note that the Committee declined to give a partisan report in the case of alternating versus direct currents. Strong pressure has been brought to bear in the way of evidence, and several desperate efforts have been made to secure the complete prohibition of high-tension alternating currents. The evidence on this subject, it is unnecessary to state, was partisan in the extreme, and it is gratifying to see that the Committee did not allow themselves to be hoodwinked, but took the very sensible ground that while high-tension currents of any kind were unquestionably dangerous, they can be made safe by proper and reasonable protection. These precautions they demand, but positively refuse to discriminate against alternating currents. The report, too, was quite definite in opposing anything like an attempt to limit voltages to be employed. The Committee virtually said to the electrical public, "Gentlemen, you are dealing with a form of energy which may be, and sometimes is, dangerous to human life. You must take care to employ it in such a way as to reduce this danger to a minimum. We do not propose to limit the voltage which you may employ; but, as you raise the voltage, you must take reasonable precautions to better the insulation." It is to be hoped that no State law covering the ground broadly will be passed, as the probable outcome will be local supervision of a kind which would protect the public without imperilling electrical interests.

The Short Series System at Rochester (N.Y.).—Electricians interested in the traction problem will watch very carefully for the outcome of a recent large contract for electric railway apparatus. This is for the City of Rochester, N.Y., and the remarkable feature of the installation is the use of the series system, which up to the present time has been very little known

Digitized by Google

in this country. Recently the Brush Company has been pushing the Short-series system, which is the only one at all well known here, and this system is very soon to be applied to the Rochester street-car lines. The plant is to be a large one, the dynamo capacity being 1,100 horse power, and 100 cars are to be fitted with motors. It seems probable from these figures that the new system will at least be given a careful and exhaustive trial on a large scale, and the result may be that it will take its place as one of the practical systems in the rapid development of electrical traction that is now going on.

The Subway Question in New York.—Electric light companies here in New York are just now making vigorous efforts to get better underground accommodation. Between the influence of the company which has a contract for subways, public dislike of having the streets torn up, and, finally, public distrust of some of the companies, electric lighting interests are having a hard time of it. Some of the figures they have recently brought to light show that a change will have to be made, and that very soon, if electric lighting is to be extended as it should be in this city. The rent which the companies are compelled to pay for the subways is unquestionably exorbitant, and the subways, even at the present high rates, are not being finished rapidly enough for the demand. But there is strong public sentiment against allowing the companies to make their own subways and tearing up the streets as often as the pavements are put down, so that the final outcome of the fight is a matter of great uncertainty.

CORRESPONDENCE.

ALTERNATE *v.* CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whilst some of those present at the reading of the Paper by Messrs. Harries and Lawrence pointed out some of the fallacies in their method of experiment, the great divergence between their results or inferences and actual practice does not seem to have been brought out. Comparing the resistance table (Table E) and the sensation table (Table F), we find that the average dry-hand resistance to the intermittent current used is 1,740 ohms, and the average current that produced muscular fixation is 3·6 milliamperes, whence the mean or effective E.M.F. required to produce muscular fixation is $1740 \times \cdot0036 = 6{\cdot}36$ volts. Ten times this ought to produce death surely. This result is, of course, simply absurd in the light of everyday experience. I have often taken shocks from Wheatstone transmitters, using 60 to 80 Daniells without inconvenience, hands dry of course. Above 100 Daniells the shock is too great; but I don't remember to have seen a case of muscular fixation with less than 80 bichromates, say 160 volts. The Wheatstone transmitter gives, of course, a truly alternating current, but with much more abrupt changes of direction than most alternating dynamos. The higher the speed of the instrument, the stronger used to be the sensation effect. Perhaps Mr. Preece could get a transmitter lent to Messrs. Harries and Lawrence for their next set of experiments.

The measurements of resistance seem open to objection—at least, the quantity measured is not a pure resistance; and probably the results given by measurements made with alternating current would be different. The human body seems to behave—as I think Dr. Stone expressed it—like a series of leaky condensers, and therefore shows a lower apparent resistance to more and more rapidly changing potential differences.

The remarks as to "make" and "break" shocks at the end of the Paper seem to indicate that the authors are really unacquainted with the alternating-current dynamos and transformers in commercial use, or are under some curious misconception as to their mode of action.

Interesting as the Paper may be to gentlemen of their own branch of the profession, it is entirely misleading as to its title and the conclusions suggested as to the dangers of commercial alternating-current plant; and it is to be regretted that it will afford a new and powerful weapon to those who are opposing electric lighting in general or certain extremely useful systems now in use.

It is difficult to understand why the Council of the Institute allowed it to pass for reading, without, at least, such an alteration of title, and such eliminations and alterations, as would have prevented its being used as a "proof" of the danger of alternating currents, and have confined it to its proper place as a contribution to medical electricity.—Yours, &c.,

Oporto, April 8, 1890. HENRY M. SAYERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the discussion now going on in your columns as to the effects of alternating and continuous currents on the human body, it seems to me not enough attention has been paid to the fact that the most deadly currents are not necessarily the most painful.

Let any one who has an induction coil where the primary is interrupted by an ordinary vibrator take from it as strong a current as he can stand without feeling real pain, the vibrations being, of course, quite rapid; let him afterwards take the current under the same conditions as to strength, but with the vibrator screwed down so as to make permanent contact, the primary current being interrupted about twice or three times a second by means of a switch worked by another person. I know a number of people who find these sudden and complete contractions of the muscles, followed by an involuntary and total relaxation, at once terminating in another dislocating contraction, more painful than the almost, if not quite, continuous contraction or tetanus produced by very rapidly alternating currents. Does this mean that these last are the least dangerous?

Death by electricity does not appear to result so much from unnatural muscular contractions as from nervous exhaustion or disorganisation of the intimate structure of the nervous substance—*not* a result of an excess of current supposed to "burn out" a nerve like an electric wire, but a result of the excessive and unnatural molecular activity of its substance (it being generally conceded that ordinary nervous activity is a molecular action). That something of this nature is what actually takes place seems to be indicated by experiments made on dissected muscles and nerves. A freshly-prepared muscle and nerve will lift a certain weight, and can be made to do a certain amount of work for a certain time, by exciting the nerve with successive electrical "shocks"; but if a very rapidly alternating current be applied, so that the muscle be permanently contracted, its lifting force soon diminishes, and if the experiment is continued *the nerve dies* at once, and no amount of repose will restore its excitability, *i.e.*, its vitality. I need hardly add that had the nerve not been subjected to the alternating current, it would have retained its vitality (if kept moist) for a considerable time, during which momentary contractions might have been repeatedly provoked.

In the above experiment we approach more nearly to the conditions of the case in question, for we have experimented on living tissues, and have been able to compare their vital resistance to various electrical conditions. It seems to me that the shortest way to settle the question would be to make a series of experiments like the above, with the object of determining the relative effects of continuous and alternating currents, and which might be extended with advantage to living animals. Until this is done, the discussion will ever tend to become like the legendary dispute of the Ancients as to whether a live fish weighed more than a dead one.—Yours, &c.,

April 16, 1890. W. O. BAILEY.

DYNAMO AND MOTOR DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the letter which you published in last week's issue from "The Writer of the Abstract," please allow me to take exception to the "few words of explanation" which he offers.

Digitized by Google

In the "authorised abstract" the sentence occurs (*The Electrician*, March 28th, p. 528), "Laminating the cores has the effect of decreasing the divergence." What I said in my remarks is given in my letter published in your issue of April 4th, so I need not repeat it; but the sentence above quoted inaccurately represents half a statement. I think this kind of incompleteness is inadmissible even in an abstract.

Again, if "The Writer of the Abstract" will compare the corrected transcript of the verbatim report which was sent to me with the re-written copy he will find that they are identical, and that the words of the verbatim report stand practically *en masse*. The statement, therefore, that I found it necessary to re-write my remarks is misleading in the sense in which it is used. I would suggest that if a proof of the abstracts of discussion was sent to each speaker, in addition to the verbatim report, all difficulties of this kind would be avoided. Nobody wants to know what any speaker was *understood* to say; what he meant to convey alone can be of any value.—Yours, &c.,

W. B. Sayers.

THE DEVELOPMENT OF ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read and re-read with intensified interest the leading article, "The Development of Electric Traction," in your last week's issue, which has incited me to make these few remarks, partly corroborating some of the statements to be found therein. As regards the application of electric motors to street-car work, it is a well-known and universal fact in the electric world that it has now passed from the elementary and experimental into the commercial and utilitarian stage. This has only been accomplished by overcoming pioneering difficulties. I do not see why the application of electric motors to railway work should not as well be brought from the elementary and experimental stage into the more advanced one of commercial utility. Giving a glance at the horse-power required for an individual street car, and likewise for an individual train, it will at once be noticed that there exists a very different ratio; and this, to a certain extent, accounts for the non-application of electric motors to railways, as motors of such magnitude have not yet been demanded. Again, taking another glance in the direction of electricity as applied to illumination in this country, as compared with its application to motor purposes, it will be remarked that the former has made greater and more rapid progress than the latter; this also partly accounts for the present state of motor development. As regards the application of the electric motor to railway work, I see no reason why, with our present knowledge and with the many skilled electrical engineers, we should not yet have our trains thus propelled. I have keenly watched the successful application of electric motors to street cars during the most inclement weather, and do not see why electric motors applied to railway work constructed on the following lines should not be as successful as those applied to street cars:—(1) The motor must be properly and strongly designed, and at the same time well adapted to its work; (2) It must be thoroughly weather-protected; (3) Its carriage and gearing must be strongly constructed; (4) An attendant left in charge must *thoroughly* understand the handling of such a motor; (5) The motor when fitted in position and put to its work must be severely tested with varying loads before it is finally accepted. I beg to emphasise the last condition. If purchasers of any kind of machinery would have it put to its work and thoroughly tested, instead of having it tested at the manufacturer's depôt, they would, I am sure, have greater satisfaction. In conclusion, I beg to state that I hope the present generation will live to see the general application of electricity to railway work. It will, perhaps, have been noticed that I have not touched on transmission of power as applied to motors for railway work; but as I have encroached to a large extent on your valuable space, I have only to say that, where water-power is available, electricity can be generated and transmitted with a high degree of commercial success.—Yours, &c.,

Gerald St. John Day.

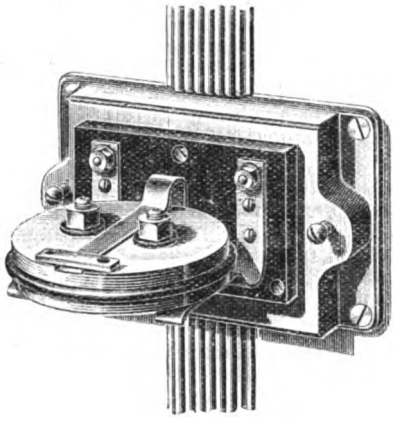
43, Polwarth-gardens, Edinburgh, April 13, 1890.

CARDEW EARTHING DEVICE.

Major Cardew's well-known automatic earthing device has been considerably modified by Messrs. Drake and Gorham. We give herewith an illustration of the latest pattern as finally adopted by the London Electric Supply Corporation after an exhaustive series of tests. The necessity for apparatus of this class was foreseen by Major Cardew some time back; and his patents, which are held by Messrs. Drake and Gorham, cover devices which depend for their action on static attraction. The static arrangement has been found to give good results, and has been adopted in the standard instrument as being less liable to derangement.

The action of the device, as is generally known, is to connect the secondary circuit to earth automatically whenever a dangerous difference of potential is established between the lamp circuit and earth. This result is obtained by interposing some medium which will be of infinite resistance until a high voltage exists, when a free passage for the current is provided.

The static device illustrated consists of two brass plates placed near, but insulated from each other. Between these lies a thin foil of aluminium, which is retained in position by ebonite pegs. One plate is connected to earth, and the other to the secondary circuit. A flat projection is formed on the upper plate, over one end of the foil, so that as soon as a difference of 400 volts is established, one end of the foil lifts by static attraction, and a metallic contact is made between the two plates. The main primary fuses are immediately severed by the increase of current, and the supply is cut off. The two plates are insulated by ebonite rings, and are securely bolted together, so that after being tested at the central station no skilled labour is required to fix them. It has been shown that the plates can be shaken or rolled about without affecting the voltage at which the foil will lift. The plates are carried by brass



Cardew Automatic Earthing Device. Front view, with cover removed

springs, to which the connections are permanently made at the back of a solid block of ebonite, so that the act of sliding in the plates makes the connections, and a slot on one side renders it impossible to put them in with the wrong side uppermost. The plates are all made interchangeable, so that when the foil has acted it is merely necessary to slide in some fresh plates.

This arrangement has a decided advantage over the method of earthing the secondary; for a strain is in this case permanently put on the insulation of the conductors, and a slight leak, which, with the automatic device, would remain harmless for years, is liable to be developed at any moment into a danger. This is specially the case in damp situations, where the size of the conductor may be reduced by corrosion.

It is evident that the apparatus can be modified to act as a relay, and cut off both poles of the circuit, or to ring a bell and drop a danger disc, as has been arranged for the Chelsea Electric Supply Company, where continuous currents are used.

In addition to the Deptford Company, the instruments have been supplied to the Newcastle Electric Supply Company; the Central Station at Lynmouth, Devon; the Shanghai Electric Company, &c.

Messrs. Baird, Thompson and Co.—This firm of ventilating, sanitary, heating, and consulting engineers, of Queen Victoria-street, London, E.C., and Bath-street, Glasgow, have purchased the patent rights and plant of the Æolus Waterspray General Ventilating and Electrical Engineering Company, and have also acquired the goodwill of the business that was carried on by this Company in Holborn, London.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS WANTED.—The Falcon Cliff Company, Douglas, Isle of Man, invite tenders for overhauling and putting in working order the electric lighting installation supplied two seasons ago. The tenders are to include working and maintaining the installation for the season, June to September, 1890. Particulars can be obtained from the Secretary.

APPOINTMENT VACANT.—The Fowler-Waring Cable Company, as will be seen by our advertising columns, require a General Manager, to undertake entire supervision, manufacture, and administrative duties. Application is to be made by letter, addressed to the Secretary, 85, Queen-street, Cheapside, E.C.

DISSOLUTION OF PARTNERSHIP.—It is announced that Messrs. Brittan and Foreman, telegraph engineers and contractors, of 21, Hermes-street, Pentonville-road, London, N., have dissolved partnership.

MESSRS. DRAKE AND GORHAM.—This firm have recently issued a well-got-up catalogue of electrical apparatus, giving illustrations, particulars, and prices of the horizontal pattern Cardew voltmeter, Messrs. Drake and Gorham's standard switch-boards, ring contact-switches, branch-way terminal-blocks and fuse-boards, excess indicators for dynamos or accumulators, battery-testers, including the Cardew cell-tester, and contact-rod for use with same. Amongst the principal users of these instruments may be mentioned—The Bank of England, the Royal Society, the Union Bank of London, the North British and Mercantile Insurance Company, the Woolwich Arsenal, the Aluminium Company (who have a standard switch-board for 4,000 amperes), the Leamington Central Electric Lighting Station, and a number of private mansions, ironclads, &c., &c. The catalogue is well illustrated.

Mr. ERNEST G. PINK.—Mr. Pink informs us that he has just completed an installation of the electric light at the new works of the Belvedere Company, Belvedere, Kent. The installation consists of two Crompton dynamos (arc and incandescent), nine Crompton arc lamps, and a large number of 16 candle-power incandescent lamps. Messrs. Crompton and Co. supplied the whole of the plant.

WOODHOUSE AND RAWSON (LIMITED).—Notice is given that the creditors of the original firm of Woodhouse and Rawson (Limited) are required, on or before the 12th prox., to send particulars of their debts or claims to the liquidators of the Company, 11, Queen Victoria-street, E.C. The solicitors to the liquidators are Messrs. Linklater, Hackwood, Addison, and Brown, 2, Bond-court, Walbrook, London, E.C.

AGRICULTURAL HALL.—During the current week a Sportsman's Exhibition and the annual show of the Kennel Club have been held at this Hall. A number of the exhibits at the recent Engineers' and Ironmongers' Exhibition were still on view, amongst them being Messrs. Paterson and Cooper's installation at the stand of Messrs. J. E. H. Andrew and Co., the Kent arc lamp installation, and the exhibits of Messrs. Crossley Bros. (Limited), the Campbell Gas Engine Company, and a few others.

COMPANIES' MEETINGS & REPORTS.

The Submarine Telegraph Company.

A meeting of the proprietors of the Submarine Telegraph Company between Great Britain and the Continent of Europe (Limited) (in liquidation) was held on Tuesday at the offices of the Company, 2, Throgmorton-avenue, London Wall, E.C., under the presidency of Sir Julian Goldsmid, Bart., M.P.

The following report of the liquidators was taken as read:—

The proprietors will recollect that they requested the liquidators to continue their negotiations with Her Majesty's Government, and endeavour to obtain a better offer for their cables. The liquidators immediately proceeded to further negotiations, but regret to have to report that they have been unable to obtain any increase in the offer for the Belgian cables, and an increase of only £3,000 for the French cables. The sum paid in respect of the Belgian cables was £9,998. 14s. 7d., and for this Company's French cables £14,999. 2s.

The sum paid for the steamer, leasehold properties, and furniture and fittings therein, was settled by valuation, and the valuation of the stores, batteries, instruments, &c., was made jointly by the officers of the Post Office and the Company.

The Belgian Government has paid the liquidators £127. 12s. 11d. for the testing huts on the Belgian coast; and the French Government has agreed to pay £1,000 for the Company's land lines in France.

The proprietors are, no doubt, aware that under the terms of the Company's French concessions, the salaries of the French clerks working the wires in the French cables had to be paid for by the companies; but, from some oversight on the part of the French Government, they omitted to send in to the companies at the time their account for the salaries of the clerks working the wires in the Havre cable from the year 1871 to 1883. The French Government discovered their omission in the course of last September. The claim was clearly one which could not be resisted by the companies, and the sum to be paid to the Government by the two companies was settled at the end of December last at £4,098, which sum, although not yet paid by the liquidators, has been charged in the accounts.

The profit realised on the sale of the securities forming the reserve fund amounted to £26,319. 5s. 9d.

With the sums paid by the Government and from the sale of the reserve fund securities, the liquidators have been able to return the capital to the proprietors in full. There now remains, as shown in the accounts, a balance of £26,840. 8s. 7d. to be yet disposed of, which will be further increased by the £2,000 caution money still in the hands of the French Government, when it is paid over to the liquidators.

A claim was made against the Company so far back as April, 1881, for alleged loss of light and air by a person occupying a house in London Wall, by the erection of the Company's premises in Throgmorton-avenue. The claim was brought before the Courts at the time, and the plaintiff was ordered to ascertain the value of the damage which he said he had sustained by the erection of the Company's premises. Instead of going on with the case, however, he let the matter drop until August last, when he resumed the action. What sum, if any, may be eventually awarded to him the liquidators are unable to say, but it should be an insignificant amount.

The liquidators now propose to make another distribution to the proprietors, to the extent of 7 per cent. of the capital, leaving in the hands of the liquidators £3,164 13s. 7d., which is subject, however, to the deduction of such sum as the proprietors may think proper to award to the liquidators for their services, and to the expenses that may be incurred until the close of the liquidation. The liquidators propose to distribute the balance remaining after these deductions, and the caution money, when they have settled accounts with the French Telegraph Administration, and with the person before referred to claiming compensation for alleged loss of light and air.

Mr. S. M. CLARE having read the notice calling the meeting,

The CHAIRMAN said that the Directors had had a hope last year that the liquidation would not take any considerable time. Hopes, however, were not always realised, and certainly they had not been in the case of the liquidation of this Company, which had taken a great deal of time, and had given much trouble. They would remember that the offer made to the Company by the French and English Governments was a very inadequate one. The consequence was that the number of interviews which he had had with Ministers and their subordinates on both sides of the Channel was very large, and the trouble the Board were put to in endeavouring to obtain a more suitable payment for the property they were handing over to the Governments was very considerable. They did get some increase on the offer originally made, but it was not so large as they would have desired. The French Government at one time was willing to extend the Company's concession, but that extension was prevented by the English Government. Then the two respective Governments changed *rôles*, the English being willing to treat them, on the whole, he would not say in a liberal, but in a reasonably fair manner; whereas the French were anxious to pay them as little as possible, irrespective of the merits of the case. Their position was this, that they were handing over a property which produced a very large and satisfactory income, and consequently they thought they ought to be paid something more than the amount at which the Governments chose to value the cables. However, they got all that they could get after a great amount of negotiations, and the result was, that, having realised the reserve fund, they were able to repay to all the shareholders the original amount of their investment in the Company. In the circumstances of the case he did not think that that was unsatisfactory. It was owing to the precaution of their having had a reserve fund that they were able to repay the whole of the capital. That fund was well invested by the Directors of the late Company, and had realised a profit of over £26,000. They proposed to distribute a further 7 per cent. of the total capital stock, which would make a return of 107 per cent. They were asked why it was that they did not wind up the Company at once. The reason was that, in the first place, the caution money, £2,000, which was deposited with the French Government years ago in order to prove that the Company were prepared to carry into effect the work which they undertook to perform had not been repaid; and in the second place they had to settle a great variety of accounts with the French Government, owing to the claims made on them by the French clerks—claims which they could not resist, and owing to the number of formalities to be gone through in connection with them, they had not been able yet to effect a settlement, although they hoped shortly to do so. The other reason was that a gentleman of the name of Bennet, who lived in a house next door to them, and who had complained that the light in his premises was so impaired by the construction of the offices where they were now assembled that he was unable to sell his pictures, had brought an action for damages for £400 against the Company, which had yet to be settled. The liquidators being of opinion that the claim was a preposterous one, thought that they would have hardly been consulting the interests of the proprietors if they did not defend the action. Having regard to the law's delay, he could not say exactly, therefore, when the accounts would be finally closed. The total amount outstanding, as they would see by the accounts, was the sum of £2,000 caution money already referred to and a balance of £3,164. 13s. 7d., which, added together, made a little over £5,000. Out of this they would have to pay the remaining expenses of the liquidation, whatever the cost of Mr. Bennet's action was, legally and otherwise, and the remuneration of the liquidators. Only one proprietor—and he was surprised that even one should have done it—suggested that two out of the three liquidators should not be paid, on the ground that they were well off. He could not entertain that opinion. They had done their duty, and he might say that he

Digitized by Google

had never taken more trouble in any business with which he had been connected than in endeavouring to get the best possible terms for the property of the Company. They were, therefore, entitled to some remuneration, the apportionment of which might be safely left in the hands of the liquidators, who could settle among themselves the proper amount due to each for the services rendered. The amount that would be given to the proprietors on the final liquidation would be 1 per cent.; that would leave roundly £1,800 for the payment of the expenses he had referred to, so that altogether in round figures they would get £108 for their £100 stock. They proposed to give 7 per cent. of that at once. He did not know that there was anything more for him to say, except that, under the circumstances, he thought the liquidation had turned out satisfactorily. They had not put the proprietors to much expense in carrying it out. He concluded by moving

"*That the report and accounts of the liquidators submitted to this meeting be approved and adopted, and that a further distribution at the rate of 7 per cent. of the capital of the Company be made to the proprietors on and after the 1st of May next.*"

The Hon. H. R. BRAND seconded the motion.

Mr. J. R. KING thought that, considering that two of the liquidators were Directors of the late Company, their services should be given gratuitously, more especially in view of the fact that there were ladies, and not a few, who had been most cruelly victimised by the winding up of the Company, which he characterised as most ungenerous treatment at the hands of the Government. Another reason why those gentlemen should not accept any remuneration was that upon a capital of £350,000 some four or five Directors had been receiving annually £2,000. Of course, he wished Mr. Clare's claim to be fairly considered, in consideration of the amount of work that that gentleman had had to perform. He was grievously disappointed at the winding up of the Company. As to the £4,000 claimed for French clerks' wages, the Directors must have been aware that the amount was due years ago, and ought not to have been charged against the Company now when it was being wound up. He wished to know also how many insulators there were in the Déolin cable, and what was the length of it.

Mr. CLARE: About 150 miles.

Mr. KING wished to know what had been received from that cable.

Mr. CLARE: We have received £12,281 for that cable, for which we had not to pay a shilling.

The CHAIRMAN explained that an agreement was made with the Paris and New York Company years ago by which that company paid for the cable. As to the item of the French clerks' salaries, owing to the fact that a new Minister was being placed in office every other nine months, the claim now made upon the Company had been omitted to be paid, although he did not know that it was the duty of the Directors to point out to the French Government that the money ought to have been paid. All he could say was that if the money had been paid before this time the Company would not have been enjoying the interest on it these nineteen years.

Mr. SIMPSON ROSTRON, while giving every credit to their late Chairman, as one of the liquidators, for what he had done for the shareholders, wished to point out that when Sir Julian Goldsmid took credit for returning the whole of their capital, he forgot to mention what chance the persons who bought, say at 220, had of getting back their money. Credit was taken for returning 107 per cent., whereas 5 or 6 per cent. of that was derived from working the concern for three months extra. He complained also of the secrecy of the negotiations between the Board and the Governments, and said that the moment the Directors saw that they were forced into a corner they ought to have thrown secrecy to the winds, and taken the shareholders into their confidence, with the view of resisting the exactions of the Government. One of their original mistakes was undoubtedly to lower their tariff at the instance of the Postmaster-General to a point below what they were entitled to charge, without making a distinct bargain as to getting their concession renewed at the end of its term.

Mr. BRAND, in reply, said that the Directors had been placed in a very disagreeable position. He had given as much as £265 for every £100 of stock which he held in the Company. At the same time he saw perfectly clearly, as every reasonable man must see, that the circumstances in which they were placed were such that neither the shareholders generally nor the Board of Directors could have avoided the disaster—if they liked to call it so—which had overtaken them. Up to within six days of the time when the English Government interposed, the Board of Directors had carried on negotiations to this point: that the French Minister had the pen in his hand to sign a renewal of the concession to the Company, and the Directors deliberately kept things secret in the belief that they were bound to succeed in their object. There had been no secrecy in the matter, and they had told the shareholders what had occurred within a week of the refusal to grant the renewal of the concession. The two last speakers complained of the action of the Government. So did he. They complained of the liquidation. So did he. But he wished to point out that the shareholders and the Directors were in a helpless position. The liquidation had been forced upon them by the Governments of France and of England. As to the remuneration of the liquidators, what the shareholders had to determine was the amount to be given, leaving to the liquidators themselves the question of its due distribution.

The CHAIRMAN said that he had gone to Paris over and over again to endeavour to get a renewal of the concession. Sir James Carmichael did the same thing, as did Sir Arthur Otway, with the result that they practically got from the French Government a promise that it would be renewed. He was unsuccessful, however, at the final moment because the English Government stepped in and prevented the signing of the contract, giving effect to the principle laid down by Mr. Fawcett when he was Postmaster-General that all the telegraphs should be in the hands of the State. Even so long ago as when Mr. Childers was Chancellor of the Exchequer he (the speaker) had endeavoured to arrange matters with the English Government, but without success.

The resolution was then put to the meeting and carried unanimously.

On the motion of Mr. THOMAS HIGHT, seconded by Mr. SIMPSON ROSTRON, it was unanimously agreed that a sum of £1,000 should be given to the liquidators for their services in the liquidation.

The CHAIRMAN next proposed:

"*That the balance in the hands of the liquidators, after the payment of all expenses, be distributed amongst the proprietors as soon as the liquidators have finally settled with the French Telegraph Administration and with the person referred to in the report claiming compensation for alleged loss of light and air.*"

Mr. ROSTRON having seconded the motion, it was agreed to *nem. con.*

The CHAIRMAN moved, and Mr. ROSTRON seconded:

"*That the books and papers of the Company—other than the account-books—as well as the books of the liquidators, be destroyed at the discretion of the liquidators after the expiration of twelve months from this date.*"

The resolution having been carried, a vote of thanks to the Chairman terminated the proceedings.

Montevidean and Brazilian Telegraph Company.

Dr. Charles Cameron, M.P., presided yesterday, at the offices, Token-house-buildings, E.C., over the ordinary general meeting of the shareholders in this Company.

The report of the Directors for the year ended December 31st last stated that the percentage of gross revenue receivable from the Western and Brazilian Company showed a slight increase, being £3,783, as compared with £3,604 in 1888. As the expenses for the year had been materially reduced, mainly because of the substitution of debentures bearing interest at the rate of 6½ per cent. per annum for the former 8 per cent. debentures, the balance to the credit of the revenue account was larger than that for any year since 1877—when the balance amounted to £2,344, as compared with £1,958 for 1889. But in 1877 only £500 was applied in redemption of debentures (instead of as now £1,000) and the large balance of £1,515 was brought forward from 1876. The percentage of earnings for 1877 amounted to £3,272, as compared with £3,783 for 1889. The Directors recommended the payment of a dividend at the rate of 4s. 6d. per share on the Preference shares, leaving a balance of £88 to be carried forward.

On the motion of the CHAIRMAN, seconded by Lieutenant Colonel G. W. MACAULEY, the report was adopted.

Bedford Electric Lighting Company (Limited).

The first annual general meeting of this Company was recently held at Bedford; Sir Henry Mance presided.

The CHAIRMAN said that the Company was formed in August, 1888, and this was practically the statutory meeting. They proposed to start in a small way, increasing it afterwards if they found it necessary, and they approached the Corporation with the object of obtaining permission, because they felt it would be useless to start a Company if the Corporation was in any way hostile to the movement. The Company offered very liberal terms, viz., that the Corporation might have the option of purchasing at cost price, or a little over, every five years, and he did not know that any more liberal terms had been offered to any Corporation by any Company in England. The Corporation could not make up their minds to give the permission, and commenced a series of investigations with the object of determining whether they could not do the work themselves. They had necessarily to wait another year, as the time had passed then for giving notice of their intention to apply for a Provisional Order; but when the time came round last year they gave notice of their intention to apply. With regard to the opposing Company in the field—the House-to-House Company—he had looked up the records at Somerset House, but found nothing to lead him to suppose that any serious opposition would be offered in that quarter. Knowing, however, that there was the possibility of other companies coming forward, they thought it best to put themselves in evidence, and they therefore issued a prospectus to assure the Corporation they were really in earnest. All they could do now was to await events. Meanwhile, they were not spending any money, and they would take care not to spend any until they were sure they could do it with advantage to the shareholders. If the Corporation made up their minds to do the work themselves, their occupation, so far as Bedford was concerned, would be gone. But his personal opinion was, that the Corporation would act very wisely if they gave it to a company, and if they did so he submitted that the local company had a greater claim to have the concern than any outside company that had recently come into the field.

Mr. Alderman Haynes, the retiring Director in rotation, was re-elected; and the meeting closed with a vote of thanks to the Chairman.

The Continental Metropolitan Tramways Company (Limited).

The third ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, E.C., on Monday, April 14th. Mr. B. H. Van Tromp presided.

The CHAIRMAN, in the course of his remarks, said that with the new concessions which the Company now possessed they had one especially favourable feature, for, amongst other things, they gave them the power to make use of electrical traction. He believed that there

Digitized by Google

was a very great future before electricity as a motive power; it was so clean and noiseless, there was no smoke, and it was so under the control of a simple-minded conductor, who could regulate the machine as easily as a child could turn a tap on or off, by simply touching a small valve. The growth of electric traction in America was so enormous that he contrasted with surprise the slow progress made in England in this direction. In the whole of England there were not 20 miles of tramway worked by electric traction. It was incomprehensible to him. In America there were no less than 1,500 miles of tramway worked by electricity, while in England we had not 20 miles. No less than 130 towns in America were served by electric traction. He was confident that electricity was the motive power for tramways from every point of view, including the vitally important point of economical working. The North Metropolitan Tramways Company in London, the Chairman of which (Mr. George Richardson) occupied a seat upon that Board, were, he was glad to say, showing some little enterprise in the matter of electric traction, and were running, or were allowing some one else to run for them, at Canning Town, experimental cars, the motive power being obtained from accumulators concealed in the cars. He learnt that the result of the working was very satisfactory, and that it was decidedly more economical than by horses. The cost of working had, he believed, been reduced by a penny per mile, from 6d. to 5d. per mile,

Mr. RICHARDSON: From 5½d. to 4½d.

The CHAIRMAN, continuing, said that there was at any rate a very distinct saving. He was glad to be able to report that an offer had been made to this Company by the Lineff Company to work a portion of their lines in Paris as an experiment by electricity, and the matter was under consideration. Under all the circumstances, he felt that it was possible that before very long there would be a considerable development of electric locomotion in Paris.

Mr. POWELL congratulated the Chairman and Directors upon the report presented and the results achieved. He was specially gratified at their obtaining the concessions referred to in the report. He had listened with satisfaction to the remarks of the Chairman on the question of electricity, with which he coincided. He, too, was astonished at the small progress made in this country in regard to electric traction compared with what had been done in America. There was, he said, a very important article in *The Times* of that day upon the subject of the progress of electric traction. He believed that the power to use electricity would prove to be a very important factor in the success of that Company. He was sure that the Directors were entitled to an exceedingly hearty vote of thanks for all they had achieved in the interests of the shareholders of the Company.

Mr. E. H. BAYLEY concurred with the remarks of the other speakers, and felt great credit was due to the Board. He regretted that the English should be so far behind the Americans in taking advantage of the use of electricity, which he felt had a great future before it; but not only was the country to blame in requiring an endless amount of trouble to be gone to, and Acts of Parliament to be obtained, but the local authorities and vestries delighted in throwing impediments in the way of tramway companies, and were not incorruptible bodies. He believed that this Company would prove a very great success indeed, and that it had a most brilliant future before it.

Mr. DUNLOP was exceedingly delighted to see the action that that Company, as representing English capital and enterprise, and French capital and enterprise too, was taking in the matter of the development of electric traction for tramways. He looked forward with considerable confidence to the future of the Company, and sincerely trusted that they would achieve the full measure of success that they deserved (cheers).

A SHAREHOLDER, who stated that he was connected with the Lineff Company, to which the Chairman had referred, said he would like to be allowed to offer a few words on the matter. He wished first of all to deal with the different methods of supplying the electromotive power to the cars; and dealing first with the system of accumulators, he desired to remark that they had been in use in Brussels for four years, but the results had not proved satisfactory; it had been found that electric traction could not be worked remuneratively by this method, and they were to be definitely discarded on May 1st. There were three other methods to which he desired briefly to refer: there was the method of conveying a continuous current to the cars by means of an overhead wire; and again, the method by an underground rail; but both of these had a variety of objections, and he was glad to be able to announce that the Company with which he was connected had now completed and perfected a system which was really invented for the benefit of this Company, by which a continuous current could be given without breaking up the roadway at all. He should shortly have the honour of inviting the Chairman and Directors of that Company to take a ride upon a full-sized car in London propelled in this manner; he hoped, within the course of a week or two.

The CHAIRMAN, in reply to a cordial vote of thanks, said he should be pleased to avail himself of the invitation to take a ride on the electric car referred to, and looked forward with confidence to the success of the experiment.

The Eastern Extension, Australasia, and China Telegraph Company (Limited).

The following are the report and accounts of the Directors of this Company for the half-year ended December 31, 1889, to be submitted to the thirty-third ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday, the 23rd inst., at 2 o'clock:—

The gross receipts, including Government subsidies, have amounted during that period to £264,105. 12s. 11d., against £238,854. 14s. 4d. for the corresponding half-year of 1888.

The working and other expenses, including £24,620. 10s. 2d. for cost of repairs to cables and expenses of ships, absorb £73,493. 19s. 3d., against £71,519. 7s. 4d. for the corresponding period of 1888, leaving a balance of £190,604. 13s. 8d. From this is deducted £2,864. 15s. 11d. for income-tax, £41,595 for interest on debentures and contributions to sinking funds, and £1,386. 7s. 3d. for additions to staff quarters, leaving £144,758. 10s. 6d. as the net profit for the half-year, which, with £26,236 1s. 8d. brought forward, shows an available balance of £170,994. 12s. 2d.

One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount, making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1889. The balance of £58,494. 12s. 2d. has been carried to the general reserve fund, which, after being credited with the interest on investments received during the half-year, and a surplus profit resulting from a careful re-valuation of the spare cable and stores in hand, and debited with £76,461. 10s. 11d. on account of the cost of the Western Australian Cable, and further partial renewals of the Hongkong-Saigon cable, now stands at £710,113. 15s. 10d.

In pursuance of the conditions upon which the issue was made, the balance of 125 of the Company's Five per Cent. Debentures (1880) was drawn by lot on the 10th ultimo for payment at par on the 1st May next. 305 of the Company's Five per Cent. Australian Government Subsidy Debentures were also drawn by lot on the 1st instant for payment at par on the 1st July next. The numbers of the drawn debentures are given on pages 12 and 13 of the report.

The subsidy agreement with the Government of the Straits Settlements in respect of the Malacca-Singapore-Penang cables expired in August last, and a fresh arrangement has been entered into for a reduced subsidy of £400 per annum payable for an additional five years.

Several cable interruptions occurred on the Company's system during the half-year under review; but as nearly all the cables are duplicated,

the traffic was not materially affected, except between Australia and New Zealand, where telegraphic communication was entirely suspended from the 7th to the 20th August. This caused some dissatisfaction in the Colonies; and, although a second cable is not required for the traffic, the existing line being more than equal to its transmission, your Directors at once decided, with the approval of the Governments of New Zealand and New South Wales, to duplicate the Sydney-Nelson cable, so as to prevent, as far as possible, any further inconvenience to the telegraphing public. A contract was accordingly entered into with the Telegraph Construction and Maintenance Company for carrying out the work, and the cable has been manufactured and shipped, and is expected to be laid by the end of the present month.

In consequence of the frequent interruption of the Madras-Penang section off Penang and in the neighbourhood of the Nicobar Islands, where the ground over which the line passes is very rocky and uneven, and to avert as far as possible the danger of total interruption of telegraphic communication with the Far East which would result from the failure of the Madras-Penang cable simultaneously with the Rangoon-Penang cable, your Directors have decided to renew a considerable portion of the Madras-Penang section, laying the new cable along a more favourable course to the south of the existing route. A contract has been made with the Telegraph Construction and Maintenance Company for the manufacture and laying of the necessary cable, 650 nautical miles in length, and it is hoped that the operation will be completed before the next south-west monsoon sets in. All the Company's cables are now in good working order.

In accordance with the Articles of Association, Charles William Earle, Esq., and Sir Thomas Fairbairn, Bart., retire by rotation, and, being eligible, offer themselves for re-election. The retiring Auditors, Mr. Henry Dever and Messrs. Welton, Jones and Co. also offer themselves for re-election.

The Indo-European Telegraph Company (Limited).

The following is the report of the Directors of this Company for the year 1889, to be presented to the twenty-third ordinary general meeting of the members, to be held at Winchester House, Old Broad-street, E.C., on Monday, the 28th instant, at one o'clock:—

The Company's revenue from all sources for 1889 amounted to £108,282. 15s. 5d., as compared with £110,327. 7s. 7d. for 1888, showing a decrease of £2,038. 12s. 2d.

The expenses were: on commercial and general account, £28,637. 9s. 3d.; on maintenance account, £30,602. 17s. 6d., including £733. 8s. 0d. paid to the Russian Government; total, £59,240. 6s. 9d., as against £52,393. 4s. 7d. for 1888, an increase of £6,847. 2s. 2d. Deducting the above expenses, taking credit for £6,783. 18s. 7d. brought over from 1888, and debiting income tax, there remains the sum of £54,535. 10s. 3d. From this ainount £10,000 has been placed to reserve, and that sum, together with £10,625, amount of interim dividend, has to be deducted, leaving a balance of £33.910. 10s. 3d.

The Directors now propose the declaration of a dividend, for the six months ending December 31st, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of Income Tax, making in all 10 per cent., carrying forward £2,035. 10s. 3d. to the credit of 1890. This dividend and bonus will be payable on and after May 1st next.

It will be remembered that the balance brought over from 1888 was larger than usual, because, as then stated, "Provision has to be made for extensive alterations and additions to the system which must be effected during the current year, and the recent interruption of both the Company's cables in the Straits of Kertch has also entailed exceptional outlay, so that the whole of the additional amount carried over will be absorbed." The amount carried over was £6,783. 18s. 7d., and the additional expenditure, as appears under "maintenance," £6,847. 2s. 2d.

The falling-off in the revenues derived from Indian messages upon the reduction of tariff, remarked upon in 1887 and 1888, continued during 1889, but fortunately has again for the most part been made up by other traffic.

The International Telegraph Conference will meet at Paris in May next. The Company will be represented as heretofore by the Managing Director.

The following Directors retire by rotation, and offer themselves for re-election:—C. Holland, Esq., and H. H. Meier, Esq.

The auditors, Messrs. C. F. Kemp, Ford, and Co., public accountants, retire, and offer themselves for re-election.

Reuter's Telegram Company (Limited).

The following is the report of the Directors of this Company, to be presented at the 26th ordinary general meeting of the shareholders, to be held at the Company's offices, 24, Old Jewry, London, E.C., on Wednesday, the 23rd inst., at 12 o'clock:—

The Directors report that the net profits for the year ended December 31st last, after payment of current expenses, and deducting rebate on unexpired subscriptions, amount to £6,703. 10s. 6d., including £446. 1s. 7d. brought forward from the last account.

An interim dividend of 4s. per share was paid in October last, and the Directors now declare a further dividend of 6s. per share, making a total distribution for the year of 6¼ per cent., free of income-tax. This will absorb £4,590. 6s., and after adding £2,000 to the reserve fund there will remain a balance of £113. 4s. 6d. to be carried forward. The dividend warrants will be payable on the 26th inst.

The important negotiations which were pending at the time of the last general meeting have been brought to a satisfactory conclusion, and the Directors have pleasure in announcing that the friendly arrangements between the Company and the leading Continental news agencies, which expired in February last, have been renewed for a prolonged period.

The Directors regret to have to announce that Mr. Frederick J. Griffiths, owing to ill-health and a heavy bereavement, has resigned the secretaryship of the Company. They have accepted his resignation with reluctance, in order to relieve him of the routine duties of the post, but they have arranged to retain him on the staff. Mr. Walter F. Bradshaw, the assistant secretary, has been appointed his successor.

In conformity with the Articles of Association, the Hon. Mark Napier retires from the direction, but offers himself for re-election. Messrs. Welton, Jones, and Co. offer themselves for re-election as auditors.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—Notice is given that the fourth drawing for payment of the Five per Cent. Debentures (1884 issue)—153 in number—will take place on Thursday, the 24th inst., at 12.30 p.m., at the offices of the Company, Winchester House, Old Broad-street, London, E.C. The receipts of this Company for the week ended April 11 amounted to £3,888.

CONTINENTAL INDIA-RUBBER GUTTA-PERCHA COMPANY.—This Company has just paid a dividend of 27 per cent. It is intended to start another factory in Austria.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants, on 1st May next, of interest for the half-year ending April 30, 1890, on their Four per Cent. Mortgage Debenture Stock. The transfer books will be closed from the 28th April to 1st May, both days inclusive.

MONTE VIDEO TELEPHONE COMPANY.—The Directors of this Company have declared an interim dividend on the Preference shares at the rate of 6 per cent. per annum for the half-year ended January 31st.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—At a meeting of the Directors held on Tuesday last, it was decided to recommend to the shareholders at the approaching general meeting that, subject to final First Preference Shares, and 27s. 6d. per share on account of arrears on the audit, a payment of 6s. per share dividend to 31st December last on the Second Preference Shares, be declared, and carrying forward £516 19s. 8d.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The directors of this Company yesterday decided, after placing £7,500 to the renewal fund, and £5,600 to the debenture redemption fund, to recommend at the forthcoming meeting a dividend of 6s. per share, free of income-tax, making with the previous dividend a distribution of £4 per cent. for the year ended December 31st, 1889, carrying forward £3,751.—The traffic receipts of this Company for the week ended April 11th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,964.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

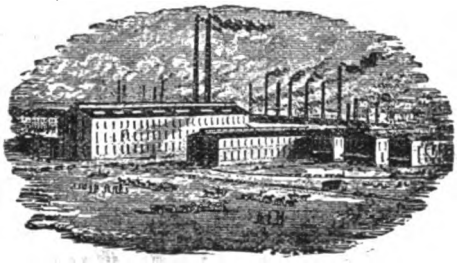
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE
ELECTRICAL ENGINEERING CORPORATION, Ltd.

(STATTER'S) **Are Proprietors of the above Patent, and Warn the Public against Infringement.** (UNITED).

The following are Licensees:—

Brush Electrical Engineering Company, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster. PERCY E. SCRUTTON, *Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 623.—Vol. XXIV. FRIDAY, APRIL 25, 1890. Price Fourpence.

NOTES.

In reviewing on Monday last the work of the Electrical Trades Section during the past year, Mr. Crompton was decidedly apologetic. The bill of fare, to use the Chairman's expression, was indeed of a very modest character; but, after all, a newly-organised body, unless it be a London County Council, is perhaps best employed during the first year of its existence in perfecting its organisation and in ascertaining in what direction its energies may be turned with the greatest advantage. The Electrical Trades Section has, however, justified its existence by good work in connection with the establishment of the British Association screw-thread as a standard, the question of railway rates for electrical goods, the collection of electrical statistics, and the Edinburgh Exhibition; and now that there has been a large infusion of new blood on the Committee, and the ground has been in some measure cleared, we may anticipate that the Section will prove increasingly useful.

A Regretable feature of Monday's meeting was the exceedingly meagre attendance. A Section which numbers considerably over two hundred members might be expected on the occasion of its annual general meeting to muster in greater strength than eleven, or, if we include the Committee, eighteen. Unless support is given to the Section, the proposals and demands of its Committee cannot carry the weight that, in the interest of the whole electrical industry, it is most desirable they should. The marked success which has attended the efforts of the Association of Municipal Corporations in regard to municipal Provisional Orders is largely due to the fact that the Association was known to have the whole of the Local Authorities of the United Kingdom behind it; and the concessions which this body has obtained from the Board of Trade certainly do not tend to diminish the necessity for an equally powerful and representative organisation on the part of the electrical trades.

The examination of Sir Benjamin Baker yesterday afternoon in connection with the Central London Railway Bill, attracted a large number of persons to the room occupied by the Select Committee. The engineer of the Forth Bridge was throughout most emphatic in testifying to the advantages and possibilities of electric traction. What he had recently seen in the States had convinced him, he said, that the time was now ripe for the solution of the municipal rapid transit problem by means of electricity.

In our correspondence columns this week will be found a communication from Otto T. Bláthy, in which he shows how to obtain the exact value for the coefficient of self-induction of a circular loop of round wire. The result is of interest, as the expressions hitherto obtained only represent the result approximately. Maxwell has, indeed, worked out the case of a circular coil of wire of rectangular section, but the expression given consists of an infinite number of terms of great and increasing complexity. Mr. Bláthy has, in an ingenious manner, succeeded in expressing the solution in a complete and comparatively simple form.

The same correspondent, in offering some criticisms on the interesting paper of Dr. Harries and Mr. Newman Lawrence, alludes to several sources of complication, causing the results stated therein to be doubtful, and subject to debate. The matter is, however, even more complex than Mr. Bláthy indicates, for the electrostatic capacity of the human body is by no means inappreciable; and this, in conjunction with its high resistance, would produce a change in the apparent resistance of the body for rapidly varying currents. The method of resistance measurement suggested by means of a Cardew voltmeter and current-meter does not, therefore, seem very satisfactory. With the remarks on the effect of testing with various electric pressures we quite agree, more especially as the body may be regarded as a leaky condenser, and subject to all the vagaries well known to occur with them.

In our present issue will be found a brief account of the latest novelty in American electrical engineering, namely, the Westinghouse alternate-arc system. It will be noticed that it consists of a return to the original series system of transformer distribution under modernised and improved conditions. The details appear to have been carefully worked out, and several safety devices are described. In order to completely avoid the introduction of high potentials into houses, transformers converting in the ratio of 1·1 are used when the same current is required in the lamps as in the main circuit. The regulation of the dynamo for constant current is accomplished by means of the alteration in lag between E.M.F. and current due to varying the external resistance; and the way in which this effect is utilised for the purpose is exceedingly ingenious. A noteworthy point is that the frequency of the current alternations has been diminished from the very high value hitherto used by Westinghouse to one more approaching usual English practice. The system will be seen to have a high efficiency at

Digitized by Google

full load, and on the whole seems to be a promising solution of the arc-light problem.

It has often been stated in American publications that when current passes from the rails to the wheels of an electrically driven car, an increase in the resistance to skidding occurs. If the assertion were true, the fact would have important bearings; for not only would it be possible to make electric locomotives lighter than others, but, as the limit of speed is largely determined by the resistance to skidding and the impossibility of making engines heavy enough, applications to express work would probably be found.

Mr. Crosby has recently tested the matter by experimenting on a car weighing about 10,000lb., the currents being passed into the driving motors both directly and through the contact between the wheels and rails. The conclusion arrived at is that there is no appreciable difference in the adhesion in the two cases, although Mr. Crosby owns that his tests were too rough to decide whether any slight difference exists or not. It is unfortunate that he had not sufficient power at his disposal to drive the car, and that, consequently, he simply found the current required to make one pair of wheels skid when the carriage springs were relieved of part of their load by jacking up the car. It is, however, difficult to see how the mere motion of the car could make any difference. There are one or two points in the experiments requiring elucidation. Thus, it was found that, when the current jumped from 20 to 42 amperes, the wheels invariably skidded whether conducting the current or not; while, if the current were increased slowly, skidding did not take place till about 50 amperes. There, however, seems no doubt about the negative result obtained, especially as in the experience of the Sprague Company nothing has occurred to warrant any other conclusion.

The determination of the ratio of the electro-static and the electro-magnetic units of electricity, although nominally a comparative measurement only, presents, nevertheless, all the enormous difficulties of an absolute determination; and the values obtained by different experimenters have exhibited very large divergences from each other. As all electrical measurements made outside laboratories are in electro-magnetic units, the ratio in question may seem of little practical value, however immensely important from a theoretical point of view; but the extensive use of alternating currents will sometimes render it desirable to ascertain the capacity of leads and other condensers whose constants are easily obtained in electro-static measure, and in such cases a knowledge of the conversion ratio will be necessary.

Until recently the value of "v" was thought to be considerably under 300; but Sir William Thomson, in a lecture which was delivered before the Royal Institution, recalled attention to the subject, and described some experiments made in his laboratory, showing that the round number 300 represented the ratio very approximately indeed. We describe in another column the most recent determination of this quantity, made in the Cavendish Laboratory by Prof. J. J. Thomson and Mr. G. F. Searle. The experiments have been performed with the minute care and extreme accuracy which we now seem to expect from the school of Cambridge mathematical physicists; and the number obtained, 299·58, will at once take its place among the valuable series of reliable constants issued from the Cavendish Laboratory.

Mr. Shelford Bidwell's Paper at the Royal Society yesterday, "On the Effect of Tension upon Magnetic Changes of Length in Wires of Iron, Nickel, and Cobalt," was a very interesting addition to our knowledge of magnetic phenomena. Mr. Bidwell has discovered the existence of critical points due to tension in elongation of the above metals when in magnetic fields analogous to the well-known Villari critical point in their permeability curves. Prof. J. J. Thomson's prediction of the non-existence of a Villari point for nickel was recently contradicted by some experiments of Mr. Herbert Tomlinson, at least for permanent magnetism; and Mr. Bidwell's results lead him to conclude that the discrepancy is due to Prof. Thomson not having taken account of the effect of tension on magnetic elongations.

Our American correspondent reports that a recent telegraph tournament has resulted in the victory of a Morse operator, who signalled 260 words in five minutes—just 52 words a minute. What will our English telegraphists say to this? One of the conditions was that the sending should be "fairly readable"—a rather vague definition; but, even with this allowance, we should not have thought that anything like 50 words a minute was possible on an ordinary Morse key, for that is a speed which only the swiftest sender on a Bell instrument, where dots and dashes are of equal length, could achieve. If the words were of average length there must be something more in the American version of the Morse code than ever we have given it credit for. As a rule, the keying in this country is, we believe, faster than in America; and we wish some of our British operators could have competed on equal terms at that New York tournament.

The one thing satisfactory about the forthcoming execution by electricity in New York is that Mr. Harold P. Brown is to be the executioner. His performance with the lower animals proved that he had great aptitude for that kind of business; and nobody has a stronger personal interest than himself—except perhaps the victim—in making sure that the job is done smartly. A handsome gratuity will be due to Mr. Brown from those interested in low-tension systems, if he is successful.

Sir Frederick Bramwell is getting over his repugnance to decimal points and watts. Only two years ago he was saying that the only idea he could attach to a "watt" was that it was the $\frac{1}{746}$ part of 1 horse-power. Yet, at his discourse on Friday night last, at the Royal Institution, on the electric welding process of Elihu Thomson, he actually spoke about the watts of power supplied electrically, and used decimal points! There is now no doubt of the enormous power of the "new force."

THE series of articles by Mr. O. G. PRITCHARD on the manufacture of "Electric Arc-light Carbons," which concludes in this present issue, will shortly appear in pamphlet form. The reprint will contain additional practical information with regard to the building and organisation of an arc-light carbon factory, and will also deal with the financial side of the question.

Exeter.—The Exeter Electric Light Company has decided to apply for a Provisional Order, and to place its wires underground.

Konigsberg.—The town of Königsberg is about to raise the sum of 1,500,000 marks (£75,000) for the purpose of building a central station.

The Eastern Telegraph Company.—The Italian agency of this Company is removed from Otranto to 28, Via Venti Settembre, Rome.

Carlsbad.—A new central electric station is to be erected at Carlsbad by Ganz and Co., of Budapest. When completed, it will be the largest station in Austria-Hungary out of Vienna.

Schallenberger Meters.—The Westinghouse Electric Company have received an order from the Metropolitan Electric Supply Company for 750 Schallenberger meters of various sizes.

Submarine Cables Trust.—Notice is given that the ordinary annual meeting of this Trust will be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, May 7th, at one o'clock.

Vegesack.—The Allgemeine Elektricitäts Gesellschaft, of Berlin, intends to light Vegesack by electricity. Already 1,500 incandescents, 25 arcs, and 8 motors have been subscribed for.

Coatbridge.—At the last meeting of the Town Council it was resolved, by 9 to 5, to consent to the Scottish House-to-House Electricity Company getting a Provisional Order for the electric lighting of the burgh.

International Telegraph Conference.—The Government of Costa Rica will send a delegate to the forthcoming International Telegraph Conference.—Colonel Mallock, Director-General of Indian Telegraphs, will represent the Indian Government at the Conference.

Mexico.—The Compania del Gas of Mexico is erecting a central station in the Pasea de la Reforma. At present the building contains a 450 horse-power Fowler engine, with five Brush dynamos, running 400 arc lamps and 2,500 incandescents.

Church Lighting.—The electric light installation at the Chapel Royal, Savoy, has been completed by Messrs. B. Verity and Sons. The schools of the Savoy have also been similarly provided. The current is supplied by the Metropolitan Electric Supply Company.

The Telegraphs in Brazil.—A Reuter's telegram of April 19 states that a new department of Public Instruction and Posts and Telegraphs has been created by the Brazilian Government, of which Senhor Benjamin Constant, at present Minister of War, has been appointed Minister

The Late Prof. Joseph Henry.—There is a proposition before Congress to pay the two daughters of the late Prof. Joseph Henry, whose valuable work in the field of electromagnetism is so well known, $20,000 as part compensation for their father's 25 years' service as a member of the Lighthouse Board.

Deaths from Electric Currents.—In reply to a question by Mr. James, Sir M. Hicks-Beach stated in the House of Commons on Monday evening that the Board of Trade had received no official information as to the number of deaths from electric currents in the United States, but were endeavouring to obtain the information.

Junior Engineering Society.—The visit of this Society to the Deptford Central Station Works of the London Electric Supply Corporation will take place on Saturday afternoon, 26th inst. The party will travel to Deptford Station, South Eastern Railway, by train, leaving Charing Cross 3 p.m., Cannon Street 3.10, London Bridge, 3.14.

Extension of the Telephone System in the North.—The National Telephone Company have just completed their trunk lines from Inverness to Dingwall and Strathpeffer *viâ* Beauly, and have opened exchanges in Dingwall and Strathpeffer, which now become the most northern points touched by the Telephone Exchange system in Great Britain.

Royal Society.—The following Papers were down for reading at the Royal Society yesterday:—Mr. W. N. Shaw, "On a Pneumatic Analogue of the Wheatstone Bridge;" Mr. Shelford Bidwell, "On the Effect of Tension upon Magnetic Changes of Length in Wires of Iron, Nickel and Cobalt;" Dr. Hopkinson, "Magnetic Properties of Alloys of Nickel and Iron."

Moss Vale (New South Wales).—On March 1st the electric light was inaugurated at Moss Vale. The contract for lighting the streets was let to Messrs. Wood Brothers and Co., electrical engineers, of Petersham. The light was completely successful. The whole of the work has been under the supervision of Mr. E. Clarence Wood, B.Sc., M.E.E. The engine is by Messrs. Robey and Co., and the dynamos by Messrs. Mather and Platt.

Brussels.—The technical committee which has for some time past had the various schemes for the electric lighting of this city under consideration, has finally decided that none of them are acceptable from the financial point of view. It has, therefore, been decided to invite new proposals, and if these do not prove satisfactory, it is anticipated that the municipal authorities will exploit the electric light as well as gas.

The Archer Electrical Conduit.—The work of preparing for the electric lighting of the Chelsea Military Exhibition, which promises to be of some interest even to electricians, is proceeding apace. The whole of the underground cables are laid in the Archer electrical conduit, which consists of a special joint on a strong stoneware pipe. The joint is on the principle of a tongue and groove, and the liquid cement poured into the side of the groove grips the tongue on all sides, and forms a perfectly water-tight conduit.

Telegraphists' School of Science.—The thirteenth annual distribution of prizes and certificates in connection with this school was held on Wednesday last week. The Controller, Mr. H. C. Fischer, occupied the chair. Attention was especially drawn to the fact that the school had again secured the first honours prize in telegraphy in the United Kingdom, as well as the medal in the "Tools" examination under the City and Guilds of London Technical Institute. Altogether 88 certificates and 68 prizes had been awarded. The distribution was performed by Mr. J. C. Lamb, Secretary to the Telegraph Department. Mr. R. W. Johnston, Postmaster of Manchester, also addressed the meeting. The proceedings terminated with a vote of thanks to the Chairman.

Gelatinous Electrolyte for Accumulators. — From the *Elektrotechnische Zeitschrift* we hear that the Oerlikon Works have for some time been using accumulators having a gelatinous electrolyte formed by treating potassium or sodium silicates with sulphuric acid. The resistance of the cell is practically the same as that of the liquid ones, and the chemical reaction is the same in both. The treatment of the cells remains as before, except that they are charged at constant potential instead of constant current. The advantages of the new form are that no gas is evolved, short-circuiting through the dislodgement of the active mass cannot occur, and breakage of the glass does not immediately incapacitate the cell. The efficiency is stated to be from 80 to 95 per cent.

The Deterioration of Insulation.—We have received from Sir David Salomons a sample of insulated wire about 30 inches long, the insulated braiding of which is completely rotten and some 12 inches of which have flaked off. The sample in question forms part of a wire 30 yards long, all of which is, we are informed, in much the same condition. The wire was laid five years ago in pitched casing, running through a dry, well-drained tunnel. The portion of the wire in the house is quite good, but the insulation is very dry, and cracks on bending. The wire, which is about No. 16, B.W.G., has only carried ·025 amperes at a

Digitized by Google

pressure of 100 volts; and it would be interesting to hear whether the above has been the common experience with good insulated wire exposed to a by no means severe trial of its durability.

Marylebone Vestry.—At a meeting of this Vestry last week, a communication was received from the Metropolitan Electric Supply Company, in which the Company accepted the conditions imposed on them by the Vestry in relation to the laying of the Company's mains (*The Electrician*, April 11th, p. 566), and asking first that no further delay occur in the commencement of the work, and secondly asking for an extension of the time expressed in the agreement between the Vestry and the Company to 18 months. After some discussion a motion was put and carried to the effect "that the application of the Company for extra time be granted, subject to the term of the resolution passed at the previous sitting being endorsed upon the agreement and passed by the Works Committee of the Vestry."

Electrical Lectures.—The following is the syllabus of Prof. Ayrton's summer course of lectures, to be given on Mondays and Wednesdays, from 4 to 5 p.m. commencing April 30th, and which are open to persons who are not regular students of the Central Institution:—"The Laws of Self and Mutual Induction and their Application to Alternate-Current Circuits, and to Circuits with Fluctuating Currents;" "Practical Methods of Measuring Coefficients of Induction;" "Practical Use of Accumulators and Transformers, in Electric Distribution;" "Direct Current and Alternate Current Transformers;" "Testing;" "Power;" "Efficiency;" "The Absolute Systems of Electrical and Magnetic Units;" "The True and So-called Legal Practical Units;" "The Construction, Laying, and Testing of Submarine Cables;" "The Determination of the Position of Faults in Land Lines and Cables;" "Simplex, Duplex, Quadruplex, and Multiplex Signalling on Land Lines;" "Combined Telegraph and Telephone Systems;" "Simplex and Duplex Signalling through Cables."

Paddington Vestry.—A special meeting of this Vestry was held on Tuesday to consider the revised report of the Electric Lighting Committee. Colonel Barchard said the revised report of the Electric Lighting Committee differed but slightly from the original report. The committee was precluded by a previous resolution of the Vestry from again opening the question of the Vestry undertaking to supply the parish with the electric light. After considerable discussion, Colonel Barchard moved, "That the electric lighting in Paddington be carried out by a company or companies to be selected by the Vestry." The resolution, on a division, was carried by 18 to 13. After an attempt to adjourn the Vestry, Colonel Barchard moved a second resolution, setting forth that, as the Metropolitan Electric Supply Company (Limited) would deposit a sum of £20,000 under section 7 of the Model Order, also that the Company had agreed to all the alterations made by the Vestry in the Model Order, &c., the Vestry be recommended to withdraw its opposito this Company for a Provisional Order. Further discussion ensued, and amendment after amendment was fought over and defeated. At last the resolution was carried, on a division, by 14 to 10. Mr. Mark H. Judge then declared that the resolution was not carried by two-thirds of the members as it ought to have been, and it was not, therefore, legal. The Chairman, however, declared the resolution carried. Originally there were six applications before the Board of Trade; but when the final decision was made, all but three had been withdrawn, the competing companies being the House-to-House, the Kensington and Knightsbridge, and the Metropolitan. The Metropolitan have agreed to supply energy at 7½d. per unit, and meters up to 50-lamp for 10s. a year. There is also to be a small charge for transformers. The question of public lighting was not considered by the Vestry.

Brighton.—At the last meeting of the Town Council Councillor Ballard moved a resolution to the effect that the Town Clerk should be instructed to write to the Town Clerk of Bradford requesting information as to the number of lamps wired, whether 5d. per unit was capable of being sustained, and what was the total cost paid by the Bradford Corporation for the installation, asking at the same time for two diagrams showing the average and maximum output of the plant. He said it appeared to him to be a matter of absolute certainty that according to the electric lighting scheme passed by the Council, they must lose £1,500 or £2,000 per year. Councillor Blaker contended that the Committee had made a mistake. The building estimate was understood to be £3,000, whereas he knew, or believed, that the work was now estimated to cost £5,755. In this building estimate alone the work would cost nearly 100 per cent. more than the estimate. If every item increased in a corresponding degree, the expense they were running the town into would be enormous. He asked them to let the matter be held over for a time. He moved as an amendment that Councillor Ballard's second notice of motion be taken with the first. It was as follows:—"That no further proceedings be taken under the resolutions as to the Electric Lighting passed at the meeting of this Council held on March 3rd, 1890 (except such of them or so far as this Council may be legally bound), until the further resolution of this Council." Alderman Ewart said he felt justified in saying that in the aggregate the tenders would not exceed the estimate, £3,000. With regard to the getting of information from Bradford, the Committee had got all the information which the Bradford Corporation were now prepared to give. He might say that the Brighton charge of 6d. per unit was established after a profound analysis by Alderman Hallett. The Town Clerk said the Brighton Company had at present an application before the Board of Trade for a Provisional Order. Should the matter be deferred, according to the motion, the application would inevitably be granted. A division was then taken on the amendment, which was lost by 17 votes to 10. The original motion was also lost.

Electric Lighting in Massachusetts.—The following particulars from the fifth annual report of the Board of Gas and Electric Light Commissioners of Massachusetts may prove interesting:—In the State there are 75 gas companies, 26 of which have the right to supply both gas and electricity, and 100 electric light and power companies, many of them recently incorporated. Only about three-fourths of the electric light and power companies were actually engaged in business at the close of the year. While the consumption of gas for private lighting is constantly on the increase in the State, its use for street lighting is decreasing each year, electric light taking its place. The electric light plants owned by gas companies are valued at $724,527, as against $341,174 in 1888. These figures are for the year ending June 30th. The total capitalisation of 102 electric light companies doing business in the State is $4,837,085. The highest capitalisation is that of the Boston Electric Light Company at $1,000,000. During the year 15 companies paid dividends varying from 1 to 21 per cent., this last including an extra dividend of 15 per cent. The total amount of the dividends was $172,372.10, which, on the basis of the total capitalisation of 102 companies, is equal to about 3·56 per cent. The first electric light company incorporated in the State was the Lowell Company in 1881, that being the only company incorporated that year. In 1882 there were three companies incorporated; in 1883 there were four companies incorporated; in 1884, one company; in 1885, three; in 1886, 13; in 1887, 14; in 1888, 31; and in 1889, 54. On June 30, 1889, the central station engine-power was equal to nearly 19,000 horse-power. The total number of arc lamps in use was 5,463, and of double-carbon lamps, 3,375. Plain carbons were used to the number of 1,086,477, and copper-plated carbons to the number of 2,776,746. The largest consumer was the Boston Electric Light Company, which used a total of 1,445,087 carbons. The total horse-power of electric motors in use on June 30, 1889, was 1,442, furnished by 538 motors, of which 111 were on arc-light circuits, 379 on incandescent-light circuits, and 48 on power circuits. The station supplying the largest amount of power was the Edison station in Boston, supplying 233 motors aggregating 623 horse-power, all on incandescent circuits. There were 2,438 incandescent lights furnished for commercial purposes off arc-light circuits. From incandescent circuits there were furnished a total equivalent of 73,386 16 candle-power lamps. At the end of the year there were 7,494 public lamps, 3,053 incandescents, and 4,441 arcs. The largest public consumer is Boston, with 935 2,000 candle-power lamps.

MAGNETISM IN IRON AND OTHER METALS.*—XV.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 592.*)

§ 66. **Magnetisation of Mechanically Hardened Iron.**—In all the examples which have been given above the iron was annealed or softened by heating to redness. Iron which has been mechanically hardened—by hammering, rolling, wire-drawing, or straining in any way beyond the limit of elasticity—shows much less permeability and susceptibility, much less residual magnetism (when tested in the form of an endless specimen), and considerably more coercive force. Thus the retentiveness of hardened iron, when in the form of a very long rod or a ring, is less than that of soft iron; but a short rod holds more residual magnetism when hard than when soft, on account of its greater coercive force.

These differences combine to give the curves of magnetisation of hardened iron a roundness of outline by which they are readily distinguished from those of soft iron.

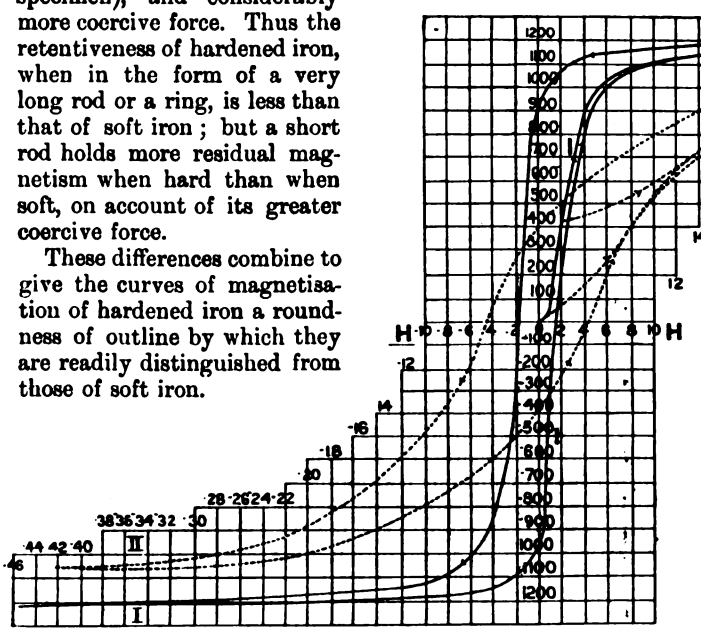

Fig. 34.—Cyclic magnetization of a soft iron wire.
(I.) After annealing. (II.) After being hardened by stretching.

The altered characteristics of the curves are well seen in Fig. 34, which shows the result of two experiments made (by the one-pole magnetometric method) on the same piece of iron wire†. In the first the wire (0·158 cms. in diameter and 60 cms. long) was annealed, and subjected to a cyclic magnetising process between the limits + 46 and − 46 of H. The results are shown by the full lines of the figure. The wire was then demagnetised by reversals, and hardened by stretching through about 10 per cent. of its original length. After the stretching weight had been removed, a cyclic process of magnetisation was gone through, the results of which are shown by the dotted lines. In this figure the ordinates are the intensity of magnetism I.

In the soft state, the maximum of susceptibility occurs early, at a force of 2·6, and its value (κ) is 245; the maximum permeability is 3,080. In the stretched state the maximum of susceptibility occurs much later, at a force of about 11, and its value is only 53: the maximum permeability is 670.

In the stretched state there is less than half as much residual magnetism as in its soft state. But stretching has increased the coercive force from 1·7 to 4·5.

§ 67. **Magnetic Qualities of Steel.**—Speaking generally, the curves of magnetisation for steel can be made to resemble closely those for iron by simply altering the scale of H. Under strong magnetic forces the region of saturation is reached in steel with much the same value of I or of B as in iron; but to reach it, or to remove it, requires the application of a stronger force. At every stage the susceptibility and permeability are less in steel, and the coercive force is correspondingly greater.

The name "steel" covers as large a variety of magnetic qualities as it does of mechanical. Beyond the differences which result from difference in chemical composition, the range is extended by the effects of mechanical treatment, and above all by the effects of annealing, hardening by quenching, and tempering. As a rule, steel which is mechanically soft or "mild" is magnetically soft, its permeability is comparatively high, and its coercive force is low; and steel which is mechanically hard is magnetically hard. Thus, if we compare samples differing in their percentage of carbon, we find, as a rule, corresponding differences of magnetic hardness; the harder samples—that is to say, those with more carbon—are less susceptible and have more coercive force. Again, as regards the effects of temper, specimens which have been hardened by quenching from a red heat are magnetically much harder than specimens of the same composition which have been annealed.

Other constituents than carbon affect the magnetic quality, often very greatly. Chromium and tungsten increase the coercive force immensely; and tungsten, in particular, is a usual constituent in magnet steel. In soft iron, as we have seen, the coercive force is about 2, or sometimes even less. In chrome steel, hardened by quenching in oil, it is 40, and in tungsten steel it may exceed 50.* These numbers are taken from a Paper by Hopkinson, which contains the most important

data at present available regarding the magnetic quality of steel. The value of his results is much enhanced by the fact that a chemical analysis of each sample is given. We shall have occasion to recur to them later, when giving collected numerical results. Meanwhile, it may suffice to illustrate the magnetisation of steel by a pair of examples taken from another source.

§ 68. **Magnetisation of Pianoforte Steel Wire.**—Figs. 35 and 36 show the results of cyclic processes of magnetisation (with positive and negative magnetic forces ranging up to nearly 100) applied to two pieces of the same pianoforte steel wire, one (Fig. 35) softened by annealing; the other (Fig. 36) glass-hardened by quenching in water from a red heat. The coercive force in the latter is scarcely inferior to that of tungsten steel. The maximum permeability is only 118; in Fig. 35 it is 295.

(To be continued.)

ELECTRIC ARC LIGHT CARBONS.

BY O. G. PRITCHARD.

(Concluded from page 570.)

Every manufacturer of carbons has, doubtless, a way of his own of coring carbons. I have experimented on three very different methods, and I now explain them. The most certain, the best, but I must also add, the slowest way, is as follows:—Take the finished carbon, and fit a small funnel, with a nozzle large enough to fit close exteriorly, partially filling the funnel with graphite powder, purified, and fired at a white heat in a graphite crucible, and then tamp the powder. With a little practice this is quickly done, but scarcely quick enough for

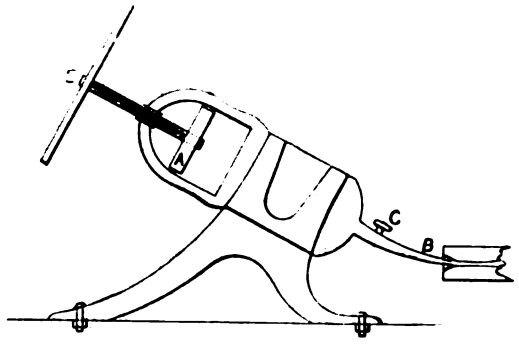

Fig. 12.—Coring Machine.

commercial purposes. The core, however, by this method can be made hard or soft, as desired. The second method is performed much more rapidly by using a specially-constructed coring machine. Before, however, describing it more particularly, I must mention certain difficulties. If the powdered graphite is mixed with water, on applying pressure with the screw the water separates, rising above the piston, whilst the powder hardens with the pressure and becomes like stone. Powdered graphite mixed with caramel fills the carbons easily, but after firing the carbon becomes harder than the ordinary lead pencil, and is spoilt. If oils are used, or liquid gums, the core is partially driven out in drying, the medium having a tendency to swell, so that the carbon is but partially filled, and the paste becomes attenuated and honeycombed when it should be close and solid, and the carbon may flicker. The only medium that answers, as far as my experience goes, is heavy mineral oil, with a specific gravity of 1·82. Mixed with this, I have not found the carbons swell nor get too hard when fired. The third and last method which I wish to mention is the gravitation method. A cask partially filled with the powder is placed under a tap of running water. This cask communicates with boxes packed with carbons by means of pipes, and as the cask runs over it fills the boxes, and the fine powder floating in the water gradually subsides, filling the core-holes. The cask requires stirring up occasionally. Where many thousands have to be cored this process will be employed, the system being automatic. The surface water should be decanted when the carbons are completely covered, and the boxes removed to the third drying-room, and left to dry, when the carbons may be withdrawn, wiped clean, and dried upon the shelves.

The coring machine (Fig. 12) explains itself. A is the piston actuated by a screw revolving upon the wheel E. C is a tap fixed to the nozzle B, which, tapering, enters the core-hole of the carbon. The finger is placed at the end of the carbon. Two or three turns of the screw will put sufficient pressure upon the material to fill several carbons, by simply turning the tap at C, which must be turned on and off as required. This method of coring must be adopted after the carbons are saturated and

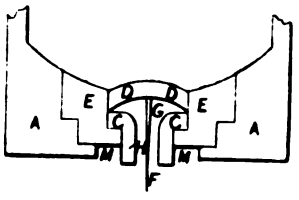

Fig. 13.—Die and Needle.

have been washed for the last time, the core hole being wet and allowing of the free passage of the paste. The pointing of the carbons is most easily effected on an emery wheel, revolving, as all emery wheels should to be of any use, at a high speed, 1,200 to 1,500 revolutions per minute.

I now come to an important matter, the construction and adjustment of the dies and coring needle. The pressure to which this needle is subjected when embedded in the pugged stuff is

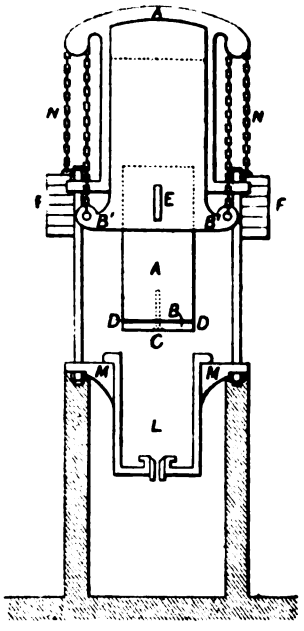

Fig. 14.—Hydraulic Press.

enormous; 120 atmospheres have to be resisted. On more than one occasion I have had the wings of my coring needle crumple up like paper; and to prevent this a proper form must be employed. A A (Fig. 13) represents the sides and base of the cylinder, E E a loosely-fitting die resting upon this base. C C is the die proper. The coring needle F must be screwed into the wings D D, which are four in number. The size of the core-hole will be determined by the size of the needle at H, no matter what the thickness of the shoulder. The die proper C C is sunk below the outer die E E, so as to allow the wings D D to find a bearing against the outer die E E. The wings are made sharp-edged above, gradually thickening to 4 mm. at the base.

Digitized by Google

The coring needle, when properly adjusted, will always be central, unless the wings get twisted by the pressure. The motive for making the die E E fit loosely is to facilitate the removal of the needle and the inner die. When necessary this is most effectually done by taking a copper tube, placing it at M M, and striking it with a heavy hammer; this will bring up the pugged stuff and the dies, instead of picking out the pugged stuff; the proper die will also be preserved from damage.

The hydraulic press (Fig. 14) which I had constructed was made of steel, but this is quite unnecessary, cast iron will do perfectly, since it will not be required to stand a greater pressure than 200 atmospheres; the ram should be 12in. diameter; and the plunger quite 8in. diameter if it is required to turn out 20,000 10mm. carbons per week. With a cylinder holding the pugged material 10in. deep, the plunger is keyed into the ram at E, so as to be removable, if necessary. The weights F F consist of iron slabs, 1cwt. each, suspended from the chains N N. Five slabs on either side are quite sufficient to raise the piston. The chains are fastened to the lugs B' B', which are part of the casting. The cylinder L with collar C drops into the framing M M, fitting tight, to prevent rocking. These parts must be made with greatest nicety. When the piston A has descended to its greatest depth it is sure to jam, unless the cylinder is strongly fixed. This may be done in many ways, and need not be explained, but must be attended to. I have employed a leverage of at least 50 tons to separate the piston from the cylinder. Not only must the cylinder be immovable, but the piston must be treated in the following manner. The piston must be lengthened, say 1¼in., by a piece screwed on to the piston end by the screw C, the head well let into a counter-sink. The addition must be a shade larger in diameter than the piston proper, with a small groove, D D, at junction. Before the piston enters the cylinder a little heavy lubricating mineral oil should be rubbed round the piston. After I had adopted this very simple plan the pugged stuff never clogged the piston higher than the groove D D, and the piston always rose unaided.

The manner of setting up the press needs no description; but being some five tons in weight, requires a good foundation. A word about the pumps. Sometimes the high-pressure pump gets out of order, a fact known by the arrested motion of the descending carbon-rod. Either the suction valve, or the cut-off valve, is out of order, or leaks. To dismount the pump is needless. Empty the tank, and wash it out with hot (not boiling) water. Throw washing soda, or soft soap, into the water, making it pass through the pump to cleanse the valves, which in time invariably become clogged with grease. The ram has constantly to be greased to keep the collar soft and pliable. Sometimes the piston of the pump requires repacking. Besides these annoyances—easily remedied—the pumps should work indefinitely.

Before I conclude I would like to mention (as it may not be thought sufficient to take the raw graphite ignorant of the amount of pure carbon it contains) a method of testing this raw material. This, indeed, should be done repeatedly, and samples kept, marked with the results of the analysis. By this means experience will be gained, and the look will almost be sufficient guide. Take and pulverise a small sample taken from the bulk, and dry it well at a temperature of 380° F., so as to make sure that all the moisture has been driven off. Take one gramme of this powder and 20 grammes of oxide of lead, also well dried; mix them thoroughly together and pour them into a hard glass test-tube, five or six inches long and half-an-inch diameter. Weigh the tube and its contents carefully, and submit the tube to a white heat under a Fletcher's blowpipe until all gases are driven off and the contents completely fused. Allow the tube to cool, and weigh the residue in the tube. The weight lost is carbonic acid, the oxygen of which has been taken from the lead oxide, while the carbon is all that there was in the graphite. For every 20 parts of loss there must have been 12 parts of carbon.

Some time ago, in hunting over patents at the Patent Office, I came across a patent (provisional) for saturating carbons. I have never tried it, but I give it here for what it is worth, and I hope not to the injury of the patentee. Steep the carbons in a dilute solution of calcic chloride, afterwards into a saturated concentrated bath of potassa chlorate (at a boiling temperature), dry afterwards by heat, and whilst hot steep in another bath of fused sodic nitrate, and wipe clean whilst hot. What effect this Turkish bath may have upon the carbons I am not prepared to say, but I think it might be worth a trial.

A NEW TESLA ALTERNATING MOTOR.

In its issue of April 9th the *Electrical Engineer* of New York describes the latest type of alternate-current motor devised by Mr. Nikola Tesla.

The motor (Figs. 1 and 2) has two laminated magnetic pole-pieces, C C', of soft iron or steel. The laminated disc-armature

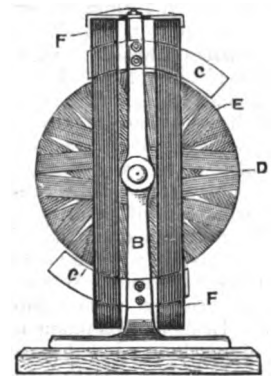

Fig. 1.—New Tesla Alternating Motor. Side view.

D is mounted between the pole-pieces C C', which are curved to conform to the circular shape of the armature. The latter is provided with a closed coil winding. The main energising coils F F are arranged so as to include within their magnetising influence both the pole-pieces C C' and the armature D, the pole-pieces C C' projecting out beyond the coils F F on opposite sides, as shown.

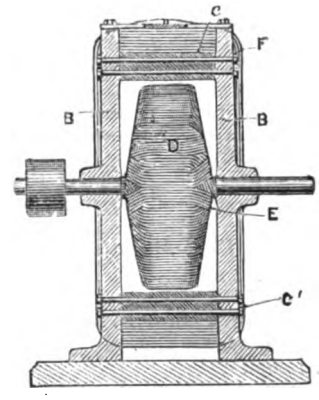

Fig. 2.—New Tesla Alternating Motor. Elevation.

If an alternating current be passed through the coils F F, rotation of the armature will be produced by the repellant force between the more closely approximating points of maximum magnetic effect. This effect is continued by the reversal of current, the polarities of field and armature being simply reversed.

One or both of the elements—the armature or field—may be wound with closed induced coils to intensify the effect. Although in the motor shown there is but one of the fields, each element of the motor really constitutes a field, wound with the closed coils, the currents being induced mainly in those convolutions or coils which are parallel to the coils F F.

RESEARCHES ON THE REVERSAL OF POLARITY OF SERIES DYNAMOS.*

BY M. A. WITZ.

Series dynamos are subject to sudden reversals of polarity, and I was led to the study of this phenomenon by coming across a machine of an extremely unstable character. I was engaged on some transmission of energy experiments, and employed for that purpose two small Edison machines, which only differed from each other in the method of exciting their fields. The generator was connected in series, while the receiver was separately excited. The machines having been started, the difference between the two E.M.F.'s remained constant so long as the opposing couple was the same. The slightest decrease, however, in the work to be done caused the receiver first to speed up, then suddenly to slow down, and finally to stop and reverse. A periodic reversal of motion then took place with surprising regularity, identically the same number of revolutions being made first to the right and then to the left. As the poles of the generator were reversed at the same time, we had the phenomenon of a periodic reversal of polarity in a series dynamo. This curious phenomenon, which I thought was unknown, had, so M. Hospitalier was good enough to point out to me, been previously observed by that distinguished physicist, M. Gerard Lescuyer, to whom in 1880 it was an inexplicable electro-dynamic paradox. To-day the phenomenon is, as I shall endeavour to show, less mysterious.

The experiment can be repeated in any laboratory with any series machine driving a magneto or a separately excited motor. If the receiver were also a series dynamo, we should have a demagnetisation of the generator, and a consequent stoppage of the receiver. The alternations of polarity and of rotation are easily produced when the magnets are of soft iron, and with some difficulty when they are of cast iron. The stronger the field of the receiver the more rapid the reversals. When the receiver is fitted with a fly-wheel the experiment is facilitated, especially if the receiver is running light. In short, this phenomenon is not peculiar to any particular type of machine; but it is easer to produce with some machines than others, and it was this consideration that induced me to carefully study the little machines which possessed such unusual sensibility.

The most singular characteristic of this periodically reversed rotation was the following. After having reversed the poles of the generator, the receiver first of all exhausted the energy stored up in its fly-wheel, and then revolved in the reverse direction until its velocity was sufficient to reproduce the phenomenon. Now, this velocity was relatively small; considerably less than that necessary to make the counter E.M.F. equal to that of the generator, as indeed the following figures will show. The generator making 1,781 revolutions, a Gramme laboratory machine attained a maximum speed of 252 revolutions; now the 252 revolutions of the receiver could only develop ·98 volt—that is to say, at the most, one-tenth of the E.M.F. of the generator. Another observation which I made is worth recording. An ammeter placed in the circuit showed that at the moment when the reversal was about to take place, the current slowly fell to zero, and then suddenly attained a value $-i$ equal to its permanent value. I would also remark that a variation in the resistance in no way contributed to the reversal of polarity.

In order to give an exact description of these various complicated phenomena, it is first of all necessary to set out the exact data of these machines.

Field Magnet.

Diameter of wire = 2·8 mm.
External diameter of the magnet = 110 mm.
Diameter of the soft iron core = 35 mm.
Height of the magnet = 234 mm.
Resistance = ·25 ohm.
Residual magnetism = 100 C.-G.-S. units.
Commencement of saturation = 12 amperes.
Strength of field at 12 amperes = 2081 C.-G.-S. units.
,, ,, ,, 14 ,, = 2124 ,, ,,
Coefficient of self-induction at ·3 amp.; $L = ·354 \times 10^9$ cm.

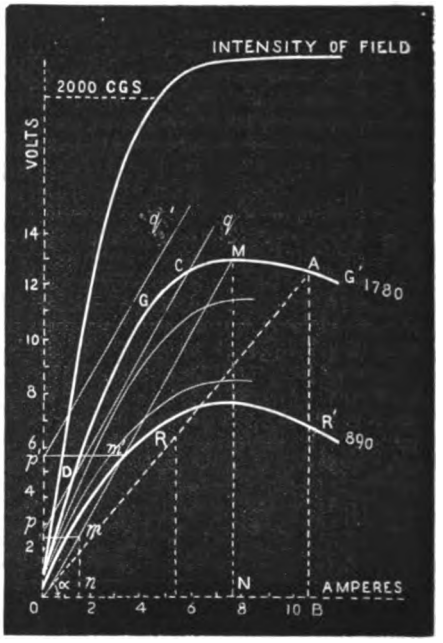
Armature.

Diameter of wire = 1 mm.
Diameter of ring = 72 mm.
Breadth of ring = 64 mm.
Resistance cold (static) = ·4 ohm.
Resistance hot (dynamic) = ·6 ohm.
Equivalent area = 72,000 sq.
Number of bars on commutator = 17.
Coefficient of self-induction for ·2 amps.; $L = ·476 \times 10^9$ cm.
Normal speed = 1780.
,, current = 7.
,, volts = 13 5.

* From *La Lumière Électrique.*

The accompanying figure shows the characteristic at 1,780 and 890 revolutions, and the curve of the strength of the magnetic field at the air-gap for various exciting currents. From the diagram it will be seen that these machines presented no anomalies; but I must call attention to their high self-induction, which explains the large difference between their static and dynamic resistance, and which, of course, is an unfavourable feature where transmission of energy is concerned, since the loss due to self-induction is equal to $N L \frac{I^2}{4}$. I will now endeavour to explain the phenomena observed.

Let us suppose that energy is being transmitted under the conditions of maximum output defined by Jacobi's law; the fields being equal, and the speed of the motor being half that of the generator, their respective curves will be R R' and G G'. The efficiency (P) of 50 per cent. will be realised if the total resistance R is equal to 1·19 ohm. In fact, if the line O M makes an angle A O B such that tan A O B = R, we can easily see that the counter E.M.F. e is half E; hence $\rho = \frac{1}{2}$. But as the resistance of the generator when at work is ·85 ohm, that of the motor ·6 ohm, and that of the leads ·25 ohm, R = 1·7 ohm and O M must be at an angle of 60 deg. Hence E = M N = 13·6 volts and $e = m n = 2·72$ volts; the efficiency being, therefore, only 20 per cent.—very bad conditions to work under, imposed by low E.M.F. of the current, and the relatively large resistance of the machines. Now draw $m p$ parallel to the axis of x, and $p q$ parallel to O M; $p q$ cuts the curve of the generator both at C and D, and the value of the current at C is its real value, which will remain constant so long as the speed of the machines does not vary. But diminish the resisting couple of the motor, and its speed will immediately increase and the ordinates of its characteristic will become higher.



The counter E.M.F. becoming greater, $p'q'$ replaces $p q$, for the two points C and D have become one; the secant has become a tangent, and there is no intersection except on the other branch of the curve; the current has also decreased to zero, and then increased negatively—the precise phenomenon observed. We can also see from the diagram that if the ordinates of the generator curve were lowered, the same result would ensue. The ordinates are lowered when the current decreases, since the strength of the field *ipso facto* diminishes. In short, this second effect is added to the first, and operates in the same direction. I observed above that the reversals were more rapid in proportion as the field of the motor was stronger. This should be so, so long as the characteristic curve of the motor rises in proportion to the increased strength of field. It can also be seen that an increase in the circuit resistance ought to have no effect, since the speed of the motor is diminished as well as that of the generator.

In short, these reversals of polarity are by the light of the diagram no longer a paradox, and we can understand how it is possible to reverse the poles of a generator by means of a motor of far lower E.M.F. than that of the generator. These considerations, however, while telling us how things happen, do not tell us why they happen. The phenomenon of the extreme instability of the magnetism of the field-magnets remains unexplained. A more stable field could no doubt be attained by employing more massive magnets and a stronger field, which would at the same time greatly increase the efficiency of the arrangement.

A DETERMINATION OF "v," THE RATIO OF THE ELECTRO-MAGNETIC UNIT OF ELECTRICITY, TO THE ELECTRO-STATIC UNIT.*

BY PROF. J. J. THOMSON, M.A., F.R.S., AND G. F. SEARLE, B.A.

The experiments made by Prof. Thompson in 1883 having given a value for "v" considerably smaller than the one found in several recent researches, it was thought desirable to repeat the experiments. The method then used was to find both the electro-static and the electro-magnetic measures of the capacity of a condenser, the electro-static measure being calculated from the dimensions of the condenser, and the electro-magnetic measure by determining a resistance which would produce the same effect as that produced by repeated charging of the condenser when placed in one arm of a Wheatstone's bridge. In the experiments in 1883, the condenser used in determining the electro-magnetic measure was not the same as that for which the electro-static capacity had been calculated, but one without a guard ring, the equality of the capacity of this condenser and the guard ring condenser being tested by the method given in Maxwell's "Electricity and Magnetism," Vol. I., p. 324.

In repeating the experiments the authors adopted the same method as before, using, however, a key of different design for testing the equality of the condensers by Maxwell's method. The results were very consistent, and practically identical with those obtained in 1883. In reply to the objection which has been made that the capacity of the leads might explain the low value of "v" obtained previously, the authors state that these are allowed for by the way the comparison between the two condensers is made, for the same leads are used in the determination of the electromagnetic measure of the capacity of the auxiliary condenser and in the comparison of the capacity of this condenser with the one with the guard ring; and the capacity of the auxiliary condenser is adjusted until its capacity, plus that of the leads, equals the capacity of the guard ring condenser; and in the electro-magnetic measurements it is the capacity of the auxiliary condenser, plus that of its leads, which is found.

As the use of the auxiliary condenser introduces additional sources of error, they endeavoured to determine the electro-magnetic measure of the capacity of the guard ring directly, using a complicated commutator, which worked both the guard ring and condenser. The first commutator used was one where the contacts were made by platinum styles attached to a tuning-fork; the results obtained with this were not so regular as could be desired, so the tuning-fork commutator was replaced by a rotating one driven by a water motor. A stroboscopic arrangement was attached to the commutator, which enabled its speed to be measured and kept constant. With this arrangement, which worked perfectly, they got values for the electro-magnetic measure of the capacity of the condenser distinctly less than those obtained by the old method. After a good deal of trouble it was discovered that in the experiments by which the equality of the capacities of the guard ring and auxiliary condensers were tested the guard ring did not produce its full effect. When the guard ring of the standard condenser was removed, and the capacity of the auxiliary condenser made the same, the two methods gave identical results; but the effect produced by adding the guard ring was less in the old method than in the new. It was found by calculation that the effect produced by the addition of the guard ring in the old method was distinctly too small, while in the new the observed and calculated effects agreed well together. The new method possesses great advantages over the old one, inasmuch as the auxiliary condenser is entirely got rid of; and since the commutator is a rotating one, its speed can be altered with much greater ease and accuracy than can be done with a tuning-fork. The old method was therefore discarded in favour of the new one.

The following are the results obtained by this method :—

ELECTRO-STATIC MEASURE OF THE CAPACITY, 397·991.

ELECTRO-MAGNETIC MEASURE.

First Set of Experiments.

No. of times the condenser is charged per sec.	Capacity $\times 10^{21}$.	No. of times the condenser is charged per sec.	Capacity $\times 10^{21}$.
64	443·427	64	443·298
32	443·571	55	443·478
48	443·523	42	443·443
80	443·459		

Mean, 443·457.

Second Set.

64	443·043	55	443·766
48	443·097	48	443·378
32	443·378	32	443·646
80	442·950	16	443·672
64	443·686	80	443·163

Mean, 443 377.

Third Set.

64	443·369	80	443·530
32	443·257	55	443·835
48	433·770	64	443·401

Mean, 443·527.

The mean of all the observations = $443·454 \times 10^{-21}$.

The means of the observations for different speeds are given in the following table :—

No. of times the condenser is charged per sec.	Capacity $\times 10^{21}$.	No. of times the condenser is charged per sec.	Capacity $\times 10^{21}$.
80	443 275	42	443·443
64	443·370	32	443·463
55	443 693	16	443·672
48	443·442		

These agree very well together, the greatest difference being about one part in 1,000.

Taking $443·454 \times 10^{-21}$ as the electro-magnetic measure of the capacity, the value of "v" is 299·58.

* Abstract of a Paper read before the Royal Society, on March 27th.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

To night) FRIDAY, April 25th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "Some Applications of Electricity in Engineering Workshops." By C. FREWEN JENKIN, B.A.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Shapes of Leaves and Cotyledons." By the Right Hon. Sir JOHN LUBBOCK, Bart., M.P.

SATURDAY, April 26th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Colour and its Chemical Action." By Captain W. DE W. ABNEY, R.E., F.R.S.

TUESDAY, April 29th.

INSTITUTION OF MARINE ENGINEERS.

7:30 p.m. Paper on "The Churchill Governor." By J. D. CHURCHILL.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Application of Electricity to Welding, Stamping, and other Cognate Purposes." By Sir FREDERICK BRAMWELL, Bart., F.R.S. Paper to be read (time permitting): "The Barry Docks." By JOHN ROBINSON, M.Inst.C.E.

WEDNESDAY, April 30th.

SOCIETY OF ARTS.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7 p.m. General Meeting.

8 p.m. Ordinary Meeting. Lecture: "Photographic Lenses." By T. R. DALLMEYER.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Conversazione.

CITY AND GUILDS OF LONDON INSTITUTE:

OLD STUDENTS' ASSOCIATION.

8 p.m. General Meeting, at Finsbury Technical College. Paper to be read on "Electric Traction." By A. RECKENZAUN, Member.

THURSDAY, May 1st.

ROYAL INSTITUTION.

1:30 p.m. Annual Meeting.

3 p.m. Tyndall Lecture: "The Heat of the Moon and Stars." By Prof. C. V. BOYS, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting. "Presidential Address" by JAMES TOMLINSON. Paper to be read: "Report upon Trials of Three Steamers, 'Fusi Yana,' 'Colchester,' and 'Tartar.'" By Prof. A. B. W. KENNEDY, F.R.S.

FRIDAY, May 2nd.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Théophile Gautier." By WALTER H. POLLOCK, M.A.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "The Distribution of Flow in a Strained Elastic Fluid," by C. A. CARUS-WILSON; (2) "Photographs of Rapidly Moving Objects;" (3) "The Oscillating Electric Spark," by Prof. C. V. BOYS.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny. Editorial, Publishing and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java Labuan Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

The rates for the United Kingdom remain as follows:— 5 0 ... 10 0 ... 19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo, 5s., postage extra.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The Directory was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which is still further enlarged and improved (making 850 pages), is NOW READY. Orders should be forwarded at once to the Publishing Offices, Salisbury court, Fleet-street, London, E.C.

WELDING BY ELECTRICITY.

Even the simplest inventions require genius for their production. Indeed, the test of a great invention seems in most cases to be its simplicity. For seventy years it has been known that if two conductors are brought together in the circuit of an electric current, the imperfect joint between them, offering resistance to the current, grows hot. The arc lamp is one case of this phenomenon, the flame which appears between the parted ends being the mere result of volatilization going on at the incandescent ends of the conducting carbons. Strangely enough, though this fact has been known so long, it does not seem to have occurred to any single soul, until three years ago, that if for the two carbons there were substituted two pieces of metal, and an end pressure applied, the two metal rods would become welded together. Yet such is, in essence, all that constitutes the invention of welding by electricity, one of the latest, but one of the most promising of electrical inventions. Professor ELIHU THOMSON, of Lynn, Massachusetts, himself, like GRAHAM BELL and EDWARD WESTON, of English birth, has brought the new art of electric welding to a high pitch of perfection. That remarkable rapidity of movement which characterises the American people when dealing

Digitized by Google

with new ideas has seized upon the electric welding process, and already has made it the basis of a growing industry. In England the mind of the average man moves more slowly. A British manufacturer hears of a new process; and because it is new he pooh-poohs it. He will wait until someone else has tried it, and lost money over it or gained, as the case may be. Not until he finds his own business suffering does he seriously think about adopting the innovation; at least, too often this is his way. But in a new country, where new things are snapped up, and tried simply because they are new, novel inventions have a much better chance of getting a fair trial on a practical scale; they flourish and become large industries in an incredibly short time. It will hardly be believed that at Lynn there exists already a very extensive factory, employing several hundred hands, not only capable of producing, but actually turning out, one welding machine per week. Yet such is the simple truth.

Nothing could well be simpler than the machinery used in the electric welding process. An alternate-current dynamo furnishes currents at a pressure of about 300 to 350 (effective) volts, and with a periodicity of 50 per second in the number of complete alternations, to the primary circuit of a transformer, which transforms them down to currents of enormously greater quantity at a pressure of only a very few volts, in the secondary circuit. This secondary or working circuit is constituted by stout copper bars, which terminate in massive copper clamps for holding the pieces that are to be welded together. One of these clamps is a fixture; the other is capable of movement to and fro, and is provided with a powerful screw motion, whereby an end-pressure can be put upon the weld. Butt-welding is the only form adopted; butt-welds made electrically being quite the equal mechanically of scarf-welds made by hand. When the two pieces are in place and pressed together the primary current is turned on. Forthwith there is induced in the secondary circuit a current which heats up the metals at the point of contact, and in a few seconds they glow and soften, and can be forced into more intimate union. As the heated surface enlarges, and the joint becomes more complete, more current flows and keeps up the heat. The process is so rapid that the heat has no time to spread. A weld between two bars having a square inch of cross-section is accomplished in 30 seconds, and the red-hot portion does not extend more than two inches on either side of the weld. It would be utterly impossible by any but an electrical method to concentrate so much energy in so short a time upon such a limited bit of material. From 12 to 20 horse-power concentrated for about 30 seconds on three cubic inches of metal are amply sufficient to raise it to welding heat. Such is the latest triumph of electric science.

In the United States electric welding machines are now being employed for a large variety of purposes: for welding iron, brass, copper and steel wire, for jointing telegraph lines, for joining iron, copper, and steel pipes from two to six inches in diameter, for welding wheel tyres, for repairing broken axles, shafts and connecting rods, for welding collars on to axles, for uniting street tram rails, for upsetting bridge eye-bars, and for making stable furniture and portions of carriages and waggons. They have also been used for making L and T joints; for welding brass safety ends to boiler tubes; for brazing in bicycle spokes, and for manufacturing steel link chain. The most astonishing feat appears to be that of splicing, by an accurate weld, wire cable such as is used in wire-rope tramway driving, the cable being fused nearly solid at the joint for about one inch of its length, but not stiffened too much to permit of its passing quite readily over the pulleys of large diameter by which it is driven. Even the operation of riveting appears to be quite within the grasp of this most valuable tool, the rivets being first placed in their respective holes and there heated and compressed *in situ*. Had the engineers of the Forth Bridge been furnished with such implements, they need not have had to carry up and down the structure any riveting furnaces; a small special appliance to be moved from point to point, and a pair of conducting wires to convey the currents, being all that they needed to drive the rivets home. It is quite conceivable that when the next big bridge comes to be built, the whole design will be different from what it would have been had the electric welding machine never been heard of. We commend the subject to the notice of Sir Edward Watkin and to all the would-be builders of high towers and big bridges. Already the possession of this new tool has had an effect on the design of bicycles. At Hartford, Connecticut, a brazing-welder has been in use for nine months, during which period it has been used for about 30,000 operations, such as brazing the two tubular limbs that constitute the driving fork into a special cast-steel socket. Forty such brazings can be made in one hour. No wonder that the managing director of these works has re-designed the entire structure of his bicycles so as to braze or weld electrically as many joints as possible.

Not only are the ordinary operations of welding thus performed, but it is even found possible to perform others hitherto deemed impossible to execute, such as the direct welding of iron to brass, the welding of cast-iron and cast-steel, and the welding to iron shanks of tools made of such intractable materials as Mushet steel and Pfeil's unweldable steel. It is probable that the aluminium industry will be directly benefited; for this material, which it has hitherto seemed impracticable to weld, or even to solder, satisfactorily, either to itself or to any other metal, is now welded electrically with the greatest ease. Indeed, it is impossible to foresee the possible applications to which this new invention may lead. Science has added one gift more to those she has bestowed on mankind; and, like her previous gifts, it is itself the harbinger of more good things to follow from the inexhaustible treasury of her wealth.

REVIEWS.

"Traité Théorique et Pratique d'Électrochemie." By Donato Tommasi. (Paris: E. Bernard et Cie.)

This elaborate work, which deserves the name of encyclopædia rather than that of treatise, is intended for the use of all persons concerned with the numerous applications of electro-chemistry. Although it consists of a series of abstracts of original researches made in various countries during the last hundred years, its aim is not so much to present an historical summary of the progress of the science, as to describe its actual state at the present time. At present there is no book dealing at all adequately with the subject which does not approach it too exclusively from the point of view either of the chemist or of the electrician. There is need for a work dealing with the matter in a more comprehensive way; and it is this need which M. Tommasi has endeavoured to meet. The numerous and important applications of electro-chemistry, such as electro-plating, electrotyping, the deposition of metals, and last, but not least, the storage of energy by secondary batteries, and the theoretical considerations involved in these matters, render the subject so vast that it is not surprising that more than 1,200 pages have been found necessary to describe them. The workers in the fields of both pure and applied science have become so numerous that it is quite impossible to read all that has been done even in one's own special department, unless the results obtained are collected in some convenient form. For this reason encyclopædias of science and its applications are very much wanted;

Digitized by Google

and M. Tommasi's book is, therefore, of great value. The work has been written quite in an unbiassed spirit. The theory of each experimenter is given with the practical results of his research. The reader is left to judge for himself between the frequently conflicting theories of the various workers. The author does not give his own views at all. It is a pity he does not do so sometimes. Each chapter begins without any general introduction to the subject of which it treats, and merely consists of a number of abstracts, without any criticism on the part of the author, or any remarks to smooth the passage from one subject to the next. It is, perhaps, far too much to expect that any one man should be able to properly discriminate between the reliable and doubtful work done in all parts of a subject of such immense range as electro-chemistry; but, all the same, it is to be regretted that this is not sometimes attempted.

The very exhaustive nature of the work will be best indicated by enumerating the twelve sections, or chapters, into which the book is divided. The first section deals with general considerations on electrolysis, and the second with movements produced in liquids by the electric current and with electric migration generally. Chapter III. is concerned with chemical combinations and decompositions produced by electrical means. Chapter IV. is devoted to a general study of the electro-chemical properties of the various elements, and the discussion of the applications of electrolysis to the deposition of various metals, such as copper, nickel, cobalt, silver, and gold. The chemical and physical properties, and the preparation of the various alloys and amalgams, are treated in the next section; and the following chapter deals similarly with mineral compounds. Chapter VII. is devoted to organic chemistry and the formation and decomposition of carbon compounds by electrical processes. In Chapter VIII. general chemical laws and chemical analysis are discussed; and Chapter IX. deals with thermo-chemistry more especially in its relations to electro-chemistry. The following two chapters discuss very fully the conductivity for electricity and heat possessed by solids, liquids and gases; and the concluding section deals with the magnetic, diamagnetic and magnetic rotary properties of different substances. A valuable appendix drawn up by W. W. Webb contains a copious list of researches on electro-chemistry made during the last hundred years. This will be of great use for purposes of reference. A very complete index, consisting of two alphabetical lists, one of authors, the other of subjects, appropriately concludes the book, since much of the practical value of such a work depends on the facility of reference to all researches connected with any particular subject.

The book is characterised by its experimental character, and by the absence of theory and mathematics. It is enriched throughout by numerous tables of valuable data. This is especially the case in the chapter on thermo-electricity. In the fourth chapter, which alone occupies 300 pages, the description of each metal is commenced with a concise table of its physical constants, such as its atomic weight, density, boiling point, melting point, specific heat, its thermal and electric conductivity, tenacity, malleability, and magnetic properties. On the other hand, matters of purely theoretical interest and those of a more practical nature are often thrown together indiscriminately, and there is nothing to guide the reader in choosing the important work from that of more doubtful value. Thus, there are twelve methods described for the production of aluminium; but the Cowles process, although one of the greatest importance, is dismissed in very few words. The work is, moreover, written rather from the chemical than the physical side; and the electrician will be frequently disappointed. Thus, when copper electrolysis is dealt with no mention is made of the researches of Thomas Gray. No theory of the action of primary batteries is given, and no mention whatever is made of secondary batteries. The chapters of most interest to the electrical reader are those dealing with electric conductivity, magnetism, and electro-optics. Here a vast number of numerical results of observations made on various substances have been brought together in an accessible form for the first time.

We can congratulate the author on the production of the most exhaustive and valuable work on electro-chemistry which has yet appeared.

"The Technical Applications of Electricity to Matters connected with Engineering." ("Die Electrotechnik in ihrer Anwendung auf das Bauwesen.") By H. Görges and K. Zickler. (Leipzig: Wilhelm Engelmann.)

The above title is a somewhat too literal translation of that of a recent German book which appears as a supplement to an exhaustive practical treatise on building construction. The subjects dealt with are electric lighting, the transmission of power and electric railways, and the applications of electricity to mining operations. The first two subjects are treated by Herr Görges, the latter only by Herr Zickler.

The work has been compiled for the use of students of engineering, and aims at giving a general, though fairly comprehensive, account of the methods by which electricity is produced and utilised for practical purposes. The authors have therefore omitted everything of a mathematical character, with the exception of here and there an application of Ohm's or Joule's law. They assume, however, that the reader has some slight acquaintance with the fundamental phenomena, such as can be got from the ordinary elementary text-books.

The first part of the book is devoted to a description of the various machines and apparatus used for producing electricity. Dynamos, motors, transformers and accumulators all receive a fair share of attention; and the descriptions are accompanied by illustrations which call for special praise, not only for their originality, but also for the accuracy of their detail. The figures and lithographed plates maintain the same high standard of excellence throughout the entire book. Much valuable space is often saved in the text by the insertion of diagrammatic sketches, showing the different methods adopted by different makers in applying the same principles. For example, there is a good series of sketches showing the shape of the field-magnet and the relative positions of the field-magnet coils and armature in the various types of dynamo. We notice a slight omission in the description of accumulators. The author does not lay sufficient stress upon the fact, though it is afterwards tacitly assumed, that an accumulator can be used with equal efficiency to send any current not exceeding the maximum prescribed value; in other words, that an accumulator is useful as a direct current transformer. Those who are not familiar with the use of accumulators often get hold of the idea that an accumulator is meant to always give a larger current than that supplied to it when charging.

In the second part, where the question of electric lighting is very fully treated, we find the different methods of distribution described in full, and the merits of each fairly discussed. The chapter of examples of electric light installations not only gives details of many large installations, but enables the author to touch incidentally upon several important points which would otherwise not come under the notice of the reader. The same remarks apply also to the third part of the book, in which the transmission of power and the kindred subject of electric railways are considered. The tables which are given of the first cost and working expenses of light installations and electric railways are valuable, as showing the approximate capital required for such undertakings, and they are based upon the careful calculations of quoted authorities. These estimates, however, all refer to the direct-current systems, and it would have made the work more complete if some reliable data had been given by which the relative cost and efficiency of the direct and alternate current systems might be compared, especially in the case of the transmission of power. Perhaps the subject of motors for alternate-current work is as yet not sufficiently developed to enable one to make comparisons of this kind; we notice, however, that no description is given of any of the existing alternate-current motors.

The fourth section, on the application of electricity to mining, has been written, as we said before, by Herr Zickler. It deals in an interesting and detailed manner with the various kinds of fuse used in mining, and the methods by which they are exploded. Some account is given of the many forms of induction apparatus used practically for this purpose. The section concludes with a comparison between the cost of firing mines in the old-fashioned way by a slow-burning fuse a metre long, and by an electric fuse with attached copper wires. He shows that the former method costs about ½d., the latter 2d. per

Digitized by Google

fuse; so that in either case the cost is trifling compared with the amount of stone loosened from the mine. The advantage of the electric method lies in the greater safety of the miner, in being able to fire the mine from a distance sufficiently great to secure him from harm.

The volume before us is one which would commend itself to English readers, not only by the fulness with which the subject is treated, but also by its conciseness, a quality which, alas! is not too often found in German works. It has also the merit of being singularly free from matter of a controversial character. We hope that before long an English translation of it will be forthcoming.

Guide to the Correction of Errors in Code (and other) Telegrams. Fourth Edition. (London: 1, 2, and 3, Salisbury-court, Fleet-street.)

The fourth edition of this valuable aid to senders and receivers of telegrams, although maintaining the same plan as the three preceding editions, has been greatly enlarged, so as to keep pace with the increasing employment of secret or code messages. The first part comprises a list of words, two or more of which, when signalled in Morse alphabet may become identical by the mere variation of the space between the signals—such variation, for example, as that which converts "man" into "mate," "grade" into "grab," and so on. Against each of these words, many thousands in number, is the Morse symbol, and the transformation to which it is liable in course of transmission. The list being prefaced by a complete Morse alphabet and numerals, not only may senders of telegrams judge for themselves the relative safety of alternative words, but receivers may correct such words as have been mutilated or disarranged in signalling. And this is a task which devolves more and more upon the patrons of the telegraph, owing to the almost universal practice of employing words which afford no clue to their identity for the guidance of the telegraph operators. Part II. comprises a much longer list of words which experience or prtacical knowledge has shown to be unsafe for code purposes, either through similarity of signals, identity in sound, or indistinctness of writing. Altogether the volume contains about 70,000 examples; and business men who use the telegraph largely, whether for inland or international purposes, will be fortunate indeed if at some time or other a work of this kind does not prove of invaluable service for deciphering inaccurate telegrams, or safeguarding against the use of words which are specially liable to be rendered inaccurately. J. L.

THE NEW WESTINGHOUSE ALTERNATING ARC-LIGHTING SYSTEM.*

This system consists in operating a constant-current main circuit which passes through converters suitable for the number of lamps to be operated at any one point. The system has been worked out in a very complete manner both as regards the dynamo, the lamps, and accessories.

The dynamo very closely resembles the Westinghouse alternating incandescent machine, but its distinguishing feature is to be found in the construction of the armature. The latter is shown in perspective in Fig. 1, and transverse sections in Fig. 2. It will be noted that in this case the armature coils are not, as heretofore, in the shape of flat coils placed on the periphery, but consist of oblong coils (Fig. 3) which are wound separately, and then by means of a clamping tool are clamped in position around the cores of the armature projections, which are provided with overlapping teeth. After the coils have been placed in position the spaces between the teeth are filled out with wooden wedges, which are dove-tailed and slid in from the side, so that no further fastening is required to keep the coils or the wedges themselves in position. The peculiar construction of the armature with the overlapping teeth has the effect of maintaining the current constant at all loads, so that there is no regulating apparatus whatever required for that purpose.

The armature is built up of thin wrought-iron sheets stamped out to the required shape; and the teeth are so designed, and are of such length, that they slightly overlap the distance between two consecutive pole-pieces, so that one tooth is not out of the field of any one magnet before another enters that field.

* From the *Electrical Engineer* of New York.

At the side of the dynamo there is an apparatus consisting of a solenoid with a single core. It is a short-circuiting apparatus, and its object is to protect the machine from the results of a break in the line. In the continuous-current machine a break in the line is generally followed by the cessation of current in the armature when a series machine is employed; but in this system a break in the external circuit causes the generation of a heavy current in the armature, which, if not prevented, would eventually cause its destruction. To avoid this the apparatus shown is employed, and its function is to short-circuit the armature. By this means the counter electromotive force generated in the armature is such as to cut down the heavy current to the normal strength, so that no dangerous heating of the armature coils can take place. The apparatus is so constructed that an excess of electromotive force generated in the armature, such as would be caused by a break in the line, causes a spark to pass between two points; this allows sufficient current to pass to energize the solenoid, which pulls up its core and makes contact between two points that short-circuit the armature.

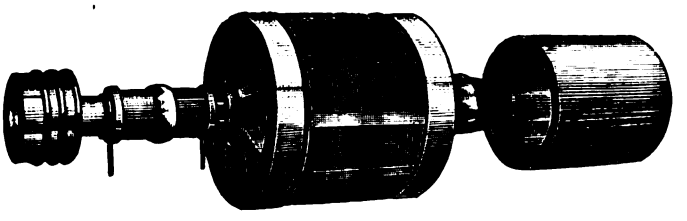

FIG. 1.—The Westinghouse Arc Light Alternator. Perspective view of Armature.

There is still another safety device of the same nature, which consists of two metal points placed opposite each other on the armature shaft and connected respectively to the collector rings. Upon the current exceeding a certain value the spark formed between these two points causes a short-circuiting of the machine, and a consequent cutting down of the current, due to the increased self-induction.

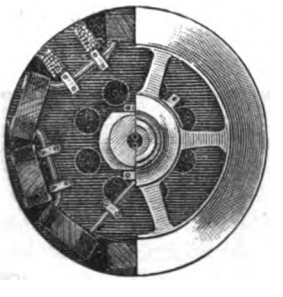

FIG. 2.—The Westinghouse Arc Light Alternator. Transverse section of Armature.

The machines now built and in course of construction vary in capacity from 25 lights to 240 lights, and the table at the end of the article shows their various sizes and capacity. It will be noted that the speeds of these machines are considerably lower than those employed in the incandescent system, and that the number of alternations per second is also far below that of the former, the average number approximating 7,500 alternations per minute, as compared with 16,000 for the incandescent machines. The machines Nos. 2 and 3 are provided with two sets of windings connected to two pairs of collectors, so that two independent circuits can be run from one machine.

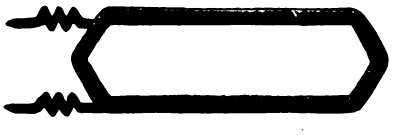

FIG. 3.—The Westinghouse Arc Light Alternator. Armature Coil.

Coming now to the apparatus intermediary between the dynamo and the lamps, we find it to consist of converters which do not, of course, differ in principle from those used in connection with the incandescent system of distribution; but for this particular purpose converters of a peculiar construction are in some instances desirable. In ordinary incandescent systems the primary and secondary of the converter are usually so designed that the ratio of reduction of potential between them is comparatively a high one, usually in the neighbourhood of 20 to 1. In this system,

Dynamo, converters and 80 lamps	288·8	85·1	64·06	10	0·801	37,860	50·7	79
Dynamo, converters and 100 lamps	290·5	101·5	80·46	10	0·805	49,150	65·9	82
Dynamo, converters and 120 lamps	285·4	111·5	90·46	10	0·754	58,980	79·06	87

however, a series of converters of various capacities are designed in which the ratio of the primary to the secondary is as 1 to 1, and in others as 1 to 3. The windings in the 1 to 1 converters are evidently identical for the primary and secondary. Though on first consideration this might be considered a curious condition, the reason therefor will become apparent when it is considered that by the employment of such converters no greater potential is admitted to a building in which there is one lamp, for instance, than is required for that particular one, and leaving the same perfectly safe to be handled, as the potential required for each lamp does not exceed 50 volts.

The lamps employed in connection with this system are of two general types, known as the long and short lamps, and designed respectively for outdoor and indoor use. The distinguishing feature of these lamps consists in the fact that they are designed to burn flat carbons whose life approximates to 40 hours in the case of the long lamp, and to a somewhat shorter period in the case of the short lamp. Thus, in the long lamps two carbons are employed, the dimensions of which are 9½in. by 2in. by $\frac{7}{16}$in. In the short lamp the length of the carbon is reduced to 6in. The mechanism of the lamp is very simple, and consists in a rack movement which is regulated by a solenoid in the main circuit, and by another of high resistance, which is placed in shunt to the arc. Both of these are provided with cores built up of bundles of fine wires, so as to avoid heating and to increase their sensitiveness.

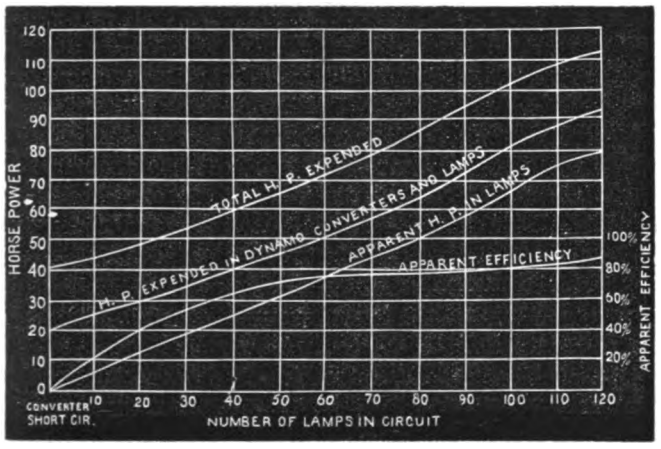

Fig. 4.

There are several accessory devices employed with the system, one of which is a double safety cut-out. This consists of the usual strips of fusible metal, but, in addition, the points which they span are shunted by a fine German-silver wire. It frequently happens that upon the fusing of the usual safety strip, an arc forms at the break, which is apt to travel backward and burn the contacts, and thus ruin the entire device before the arc is broken. By employing the German-silver shunt around these points the fusing of the fusible strip immediately sends the current through the shunt, which at once fuses, breaking into small pieces and forming directly a break of six inches between its terminals—a distance which the arc is incapable of following.

A series of tests have been made on this system, showing its efficiency under various conditions; and for that purpose we give above a table showing the results of a test carried out at the works of the Westinghouse Electric Company in Pittsburgh. These tests were made on a No. 2 30-ampere machine, operating 120 lights. The engine was of the Westinghouse single-acting two-cylinder type, the diameter of the cylinder being 14½in. and the length of stroke 30in. The curves shown in Fig. 4 represent graphically the results given in the table. From these it will be seen that the machine at very light load has a comparatively low efficiency; but beginning with forty lamps up to the full capacity the efficiency rapidly increases until at full load it approximates 87 per cent., and the energy per lamp required is ·75 horse-power.

In further explanation of the action of the machine we may add that the regulation for constant current depends primarily upon the fact that the armature is wound with a sufficient number of turns to produce a high self-induction, and consequently a lag in the current approaching 90 deg. when short-circuited. According to a well-known law, the current lag, as related to the impressed electromotive force, is reduced by the introduction of resistance into the circuit, and approaches coincidence with the phase of electromotive force as its limit. The magnetisation of the field is so related to that of the armature that when an armature pole is opposite to a field pole, and the magnetising effects are in contrary directions, the resultant magnetisation is reduced to a very small amount. These two elements combine to produce an effective cutting of lines of force approximately proportional to the external resistance in the following way:—When the armature rotates with a high resistance in circuit the lag is small, and the maximum current flows in approximate coincidence with the maximum of electromotive force; that is, when an armature pole is an intermediate position between two field poles. The direction of current is opposite to that in the field coils of the pole it is approaching. In other words, the maximum point in the current phase occurs about 90deg. in advance of the coincidence of two poles of similar polarity. A reduction of resistance in the work circuit causes a lag in the current phase, so that the maximum point is reached at an instant in time more nearly coincident with the opposition of similar poles; and when the armature coils are short-circuited and the lag reaches its maximum, the magnetisation of the armature-pole occurs approximately at the time of its passage under a field-pole of opposite polarity. Since the windings of the field and armature are such as to set up approximately equal magnetic potentials in opposite directions, the cutting of lines of force is now reduced to a minimum value sufficient to cause the flow of a normal current through the coils. The current characteristic of the machine can be made to approach as nearly to constancy as can the electromotive force characteristic of a constant potential dynamo with varying current.

ELECTRIC WELDING.*

BY SIR FREDERICK BRAMWELL, BART., F.R.S.

Tolerably correct definitions can generally be given, the lecturer said, of the more commonly-used technical terms, such as "stereotyping," "safety valve," &c.; but he doubted very much whether most people had any clear conception of what was meant by welding. Welding was not fusing or burning; it was the uniting of two pieces of metal by the aid of heat and pressure. The lecturer then quoted from Dr. Percy in order to show how extremely difficult it was to hit off in metals other than the recognised weldable metals—iron, steel, and platinum—the proper welding temperature, and to effect the weld while the metal was at that temperature. The three welds, the scarf, double-wedge, and butt, formerly employed in the making of wheel-tyres, were next described. The heating of the metal to be welded had hitherto been done in the smith's fire, which was in its way a perfect work of art, a grotto of coal with a fire inside it, in which the thing to be heated could be put. This way of going to work was obviously defective. First of all it was dirty; then the heat was not easily regulated; and, lastly, the heat was by no means uniform throughout. The heat was from the outside inwards, and therefore while the external layers of the metal might be much too hot, the inside

* Abstract of lecture delivered at the Royal Institution, April 18th.

Digitized by Google

might be quite "raw," so to speak. The desiderata in welding were (i.) Uniform heating through the entire section ; (ii.) Regulation of the heating ; (iii.) Freedom from dirt ; (iv.) Ability of inspection during heating. All these requirements were practically fulfilled if electricity was used as the source of heat.

In electric welding, the lecturer said, we were only concerned with the strength of the current, and not with its difference of potential. The fact that the heating effect varied as the square of the current was then demonstrated by placing four incandescent lamps in series across a constant potential circuit, and cutting them out successively until only one remained, when it was seen to give a glow far exceeding four times that which it did at first. The fact that different metals possessed different specific resistances was then shown by sending the same current through lengths of copper, iron, and German-silver wire. Another fact to be remembered, said the lecturer, was that the resistance of metals increased with their temperature. The advantage of this phenomenon in connection with welding was then emphasised by the lecturer, who pointed out that it tended to produce the great desideratum, uniform heating ; since the increased resistance of the more highly heated portions of a weld caused the current to seek the cooler portions, and thus a nearly uniform temperature was attained throughout the entire area of the weld. Iron (with its ally, steel), which was the most important of all metals from a welding point of view, was very fortunately situated in this respect, since its temperature-coefficent of resistance was exceedingly high ; the resistance of soft iron wire at 1,000° C. being eleven times its resistance at 0° C.

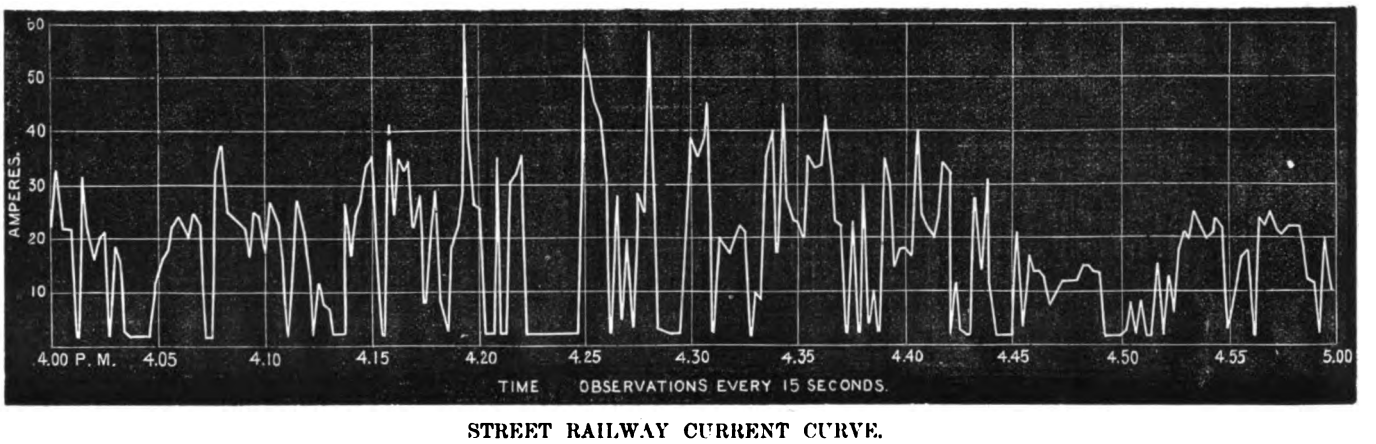
The lecturer then explained how electrical energy was made up of two components—the amperes and the volts. Now the electric welder, he said, required a large current and low voltage, while to transmit electric power without undue loss a small current of high voltage was required. If, therefore, it was impossible to generate the current close to the welder, some instrument was wanted by which we could transform the high-voltage current into one of large quantity and low voltage at the electric welder. Such an instrument was available in the alternating-current transformer, the principle of which was made clear by the aid of experiments with two Ruhmkorff coils, the original source of energy being five primary cells. The five cells were connected to the primary of the first coil, the secondary of which passed through a small incandescent lamp, but without causing it to glow : this secondary was connected to the secondary of coil No. 2, in the primary of which another lamp was placed, and was made to glow brightly. This, said the lecturer, was an example of the way in which a high-voltage and small-amperage current can be used for transmission purposes, and then can be transformed down to a low-voltage and large-amperage current for heating purposes.

Several welds were then effected by a small Elihu Thomson electric-welding machine, the lecturer having previously described the peculiar form of alternating-current transformer used in welding on a large scale, and the methods of regulating the current either by altering the resistance in the exciter circuit of the dynamo, or by using a "reactive coil" (*The Electrician*, August 30, 1889, p. 422), placed in the primary of the transformer. Referring to some experiments which he had undertaken with a view of testing the value of this method of welding, the lecturer stated that he had procured for the purpose a large number of pieces of Farnley round iron, 1⅛in. in diameter and 14in. long. These were sent to the electric-welding works at Fanshaw-street, and on a certain day the operation of welding these was commenced, at 11:45 a.m., and was continued until eighty welds had been made. This was effected by 3:24 p.m., or, allowing for a rest of half-an-hour, three hours and nine minutes, giving an average of a little under two and a-quarter minutes per weld. The smith and hammerman were electricians, and not smiths, so that they laboured under considerable disadvantage. With the object of making direct comparison, portions of the same lot of iron were welded in the ordinary manner by skilled labour. In this case also the work was continued for three hours, in which time forty-four welds were made, or a little under four minutes to a weld. The pieces were then numbered, and sent for experiment to Mr. Kirkaldy's testing works. From these it appeared that the strength of the metal being originally 52,646lb. per square inch, that of the electrically welded pieces (where they broke at the weld) was 48,215lb., or 91·9 per cent. of the original strength ; while in the case of the hand-made welds the corresponding figures were 46,899lb. and 89·3 per cent. As an instance of the complete control which could be attained when welding by electricity, pieces of copper, aluminium, and German-silver wire were welded by the Thomson automatic welder (*The Electrician*, August 30, 1889, p. 422), which automatically cut off the current as soon as the weld was effected.

In conclusion, the lecturer stated that he was of opinion that Prof. Elihu Thomson's great invention would be used rather to effect what might be termed extraordinary welds, in which direction it was so efficient, than in ordinary welding operations ; and that the fact of the existence of such a machine would open up many new uses.

A STREET RAILWAY CURRENT CURVE.

The fluctuations of the ammeter at the power stations of street railways have been much commented on. What these fluctuations may amount to, especially where only a few cars are operated, is most forcibly brought out by the following curve, which we take from the *Electrical Engineer* of New York. The curve represents the ammeter record at the power station of the Sprague electric railway at Brockton, Mass. It gives the readings with three cars on the line, and brings out very strongly the severe conditions which are met with in this kind of work.



STREET RAILWAY CURRENT CURVE.

THE LONDON CHAMBER OF COMMERCE (INCORPORATED).

The annual meeting of the Electrical Trades Section of this Corporation was held on the 21st inst., at the offices, Botolph House, Eastcheap ; Mr. R. E. Crompton in the chair.

The SECRETARY (Mr. R. Kenrick Murray) read the minutes of the last meeting, which were confirmed, and signed as correctly entered.

The CHAIRMAN then explained that it had been decided to increase the number of the committee from 33 to 48 members, the number which was arranged for at the formation of the Section ; so as to get an infusion of new blood into it, and thereby increase its usefulness. The committee, as newly constituted, would therefore consist of the following gentlemen :—

Telegraph Companies (7).

Sir John Pender, K.C.M.G. (Eastern Telegraph Company, Limited).
Mr. J. H. Tritton (Indo-European Telegraph Company, Limited).
The Marquis of Tweeddale (Eastern Telegraph Company, Limited).
Mr. C. W. Earle (West India and Panama Telegraph Company, Limited).
Mr. R. K. Gray (Spanish National Submarine Telegraph Company, Limited).
Mr. H. Weaver (Anglo-American Telegraph Company). (Away.)
One vacancy to fill.

Digitized by Google

TELEPHONE COMPANIES (4).

Colonel R. R. Jackson (National Telephone Company, Limited).
Mr. H. Grewing (Oriental Telephone Company, Limited).
Mr. J. Brand.
Mr. J. W. Batten.

ELECTRICAL MANUFACTURERS AND CONTRACTORS (20).

Mr. R. E. Crompton (Messrs. Crompton and Co., Limited).
Mr. Alex. Siemens (Messrs. Siemens Brothers and Co., Limited).
Mr. M. Immisch (Messrs. Immisch and Co.).
Mr. E. Garcke (Brush Electrical Engineering Company, Limited).
Mr. F. L. Rawson (Woodhouse and Rawson United, Limited).
Mr. B. Pell (Messrs. Johnson and Phillips).
Mr. C. J. Wharton (Messrs. Laing, Wharton and Down).
Mr. W. O. Callender (Callender's Bitumen Telegraph and Waterproof Company, Limited).
Mr. B. Drake (Messrs. Drake and Gorham).
Mr. W. T. Goolden (Messrs. W. T. Goolden and Co.).
Major S. Flood Page (Edison and Swan United Electric Light Company, Limited).
Mr. G. Binswanger (General Electric Company).
Mr. James Swinburne (Messrs. Swinburne and Co).
Mr. James Taylor (Telegraph Manufacturing Company).
Mr. W. L. Madyen (Electrical Engineering Corporation, Limited).
Mr. R. J. Jenkins (Henley's Telegraph Works Company, Limited).
Mr. Paterson (Messrs. Paterson and Cooper).
Mr. Joseph Smith (Electric Construction Corporation, Limited).
Messrs. Spagnoletti and Crookes (not replied).
Mr. Sidney Sharp (Messrs. Sharp and Kent).

ELECTRICITY SUPPLY COMPANIES (9).

Major-General Webber (Chelsea Electricity Supply Company, Limited).
The Earl of Crawford (London Electric Supply Corporation, Limited).
Mr. R. Wallace (Westminster Electric Supply Corporation, Limited).
Mr. R. S. Erskine (Kensington and Knightsbridge Electric Lighting Company, Limited).
Mr. Jos. Crookes (Notting Hill Electricity Supply Company, Limited).
Mr. Robert Hammond (House-to-House Electric Light Supply Company, Limited).
Mr. S. F. Dobson (St. James's and Pall Mall Electric Light Company, Limited).
Mr. H. G. Massingham (Taunton Electric Lighting Company, Limited).
One vacancy to fill.

CONSULTING ELECTRICAL ENGINEERS, AND GENERAL (9).

Mr. J. E. H. Gordon.
Mr. W. H. Preece.
Mr. G. Kapp.
Mr. H. Sherley Price.
Mr. Musgrave Heaphy.
Mr. F. T. Medcalf.
Mr. W. Worby Beaumont.
Mr. H. Lea.
Prof. Geo. Forbes.

The CHAIRMAN concluded by moving their election *en bloc*.

The motion was seconded by Major-General WEBBER, and agreed to unanimously.

Colonel R. R. JACKSON expressed a wish to withdraw his name; but, at the request of Major-General WEBBER and Mr. E. GARCKE, both of whom bore high testimony to the value of his services to the Section, he was induced to continue to serve.

The CHAIRMAN here took occasion to refer in feeling terms to the death of Mr. W. H. Snell, late Editor of *The Electrician*, and remarked that by the demise of that gentleman not only the whole electrical profession, but this Section of the London Chamber of Commerce in particular, in the proceedings of which Mr. Snell took a keen interest, had sustained a great loss. The Chairman then went on to say that it was now his duty to vacate the chair to which they had done him the honour to elect him last year. He regretted very much the fact that he had perhaps somewhat inadequately filled the post; but it was not quite so easy a task as it might seem at first sight. His successor would, no doubt, find it very much easier, because they had got into somewhat better working order than they were at first. They had a very modest bill of fare to put before the members, and there were still a few matters in hand which he hoped would soon be completed. One of the solid things that they had done during the year had been with regard to establishing the British Association screw-thread as a standard type for apparatus and screws; and if they could only get gun-makers and clock-makers, and the screw trade to take up the matter as the Section had done, it would be seen that something had been done towards making the standard popular. Another achievement, which had been his own child to a certain extent, had been the starting of a sort of statistical society for collating electrical statistics; and he hoped that it would result in bearing valuable fruit to the electrical industry. There could be no doubt that they were in want of accurate knowledge of what was being done all over the world in respect of electrical science; and it was to be hoped that if they gave the results of their experience and information to their neighbours, the benefits derived therefrom would be duly appreciated and reciprocated. With regard to the screw gauge question he might say that Mr. Trotter had called on Mr. H. J. Chaney, the keeper of the Board of Trade standards, who had consented to allow comparisons of screws and gauges of the British Association standard to be made at the Standards Office, 7, Old Palace Yard, Westminster, by any person making an appointment with him for that purpose; and who was prepared to consider the matter of making the screw gauge a legal gauge; and it was therefore to be hoped that in the course of next year they would succeed in accomplishing that. Another matter in which Mr. Garcke had rendered substantial service was with regard to the railway rates, as to which they had obtained, with the exception of one or two matters yet undecided and of minor importance, most of the advantages they had hoped to receive. He trusted, now that they had a larger committee, that the attendances at their meetings would be larger than had hitherto been the case, so as to enable them to effectively carry on the useful work in which they had embarked.

Major-General WEBBER expressed his satisfaction at the statement just made by the Chairman. The work that had been done by the Section, as had been rightly observed, had been in directions of a very important character; and if it had not been quite so successful as might have been expected, they must not forget that this was the first year of the existence of the Section, and that a great deal of the time of the Committee had been taken up in organisation and in finding out the different directions in which their labour might be profitably and usefully exercised in the interests of electrical industry. Mr. Crompton had referred to his successor; but he (the speaker) having attended the meetings as frequently as he could, was a witness that no one could be a better Chairman than Mr. Crompton himself, or could take a greater interest in the subjects which were now engaging their attention. He, therefore, would propose that they should unanimously invite Mr. Crompton to undertake the duties of the chair for another year.

Colonel JACKSON said he had great pleasure in seconding the proposal, and paid a warm tribute to Mr. Crompton for the way in which he had fulfilled his duties during the past twelve months.

The motion was carried unanimously.

Mr. CROMPTON, assuming the chair for the second time, expressed his appreciation of the compliment paid to him, and assured them of his intention to do all that he could in the interests of the Section, which he hoped would be instrumental in effecting some useful work in the future.

On the motion of Mr. SWINBURNE, seconded by Mr. BEAUMONT, Mr. E. Garcke was elected Deputy-Chairman, together with Major Flood Page, the other retiring Deputy-Chairman.

Mr. GARCKE, in returning thanks, said that he would willingly assume the duties provided that Lord Crawford, who now retired, did not see his way to resume office.

A discussion on the subject of the labour conciliation scheme followed, in which some of the most prominent difficulties in connection with the subject were set forth by the Chairman, Col. Jackson, Mr. Stephens, Major-General Webber, Mr. Applegarth, and Mr. Trotter.

Colonel JACKSON then proposed, and Mr. R. S. ERSKINE seconded,

"That the thanks of the Section be given to the gentlemen who had elaborated the scheme for the adjustment of labour disputes, and that the Section undertakes to co-operate in the proposed plan of co-operation, and that it instruct its committee accordingly."

The motion was agreed to *nem. con.*; and the Chairman having been thanked for presiding, the proceedings terminated.

CENTRAL LONDON RAILWAY BILL.

HOUSE OF COMMONS.—MONDAY, April 21st.

On Monday last a Sub-Committee of the House of Commons, consisting of The Hon. Walter James (in the chair), Mr. Esslemont, Colonel Bridgeman, and Sir Walter Grey, began an inquiry into the scheme for constructing an underground railway from Uxbridge-road along Oxford-street, terminating close to the Bank of England.

Mr. Pember, Q.C., Mr. Saunders, Q.C., Mr. Freeman, and Mr. Monroe appeared for the promoters; and a numerous Bar, representing some 30 or 40 opponents on the line of route, who opposed on different grounds. The principal counsel were Mr. Pope, Q.C., Mr. Littler, Q.C., Mr. Cripps, Q.C., Mr. Vane, Q.C., Mr. Rose-Innes, Mr. Freeman, Mr. Pollock, Mr. Danckwerts, &c., &c.

Mr. PEMBER, Q.C., opened the promoters' case. He said the length of the line was four miles and a half; the depth at which it would be under the streets of the City averaged about 50ft. The depth was greater towards the City, and it was not unimportant that in very few instances did it pass under buildings, and it was worked in the same way as the Southwark Subway. The capital was £2,500,000, with a borrowing power of £833,000, making a total of £3,333,000; but that was now reduced by some £90,000 intended for a junction with the Southwark Subway, which part of the scheme had now been abandoned. The tunnel would be encased in iron throughout, and "grouted" with blue lias, which would give enormous strength and durability to it, and absolutely prevent again any chance of subsidence. Then there would be hydraulic lifts at the different stations, on a similar plan to those adopted in the Mersey Tunnel and the Glasgow Subway under the Clyde. The speed they expected to attain would be 25 miles an hour; but including stoppages it would be considerably less, about 14 miles an hour, which would take people from the Marble Arch to the Bank in something under a quarter of an hour, or about three times as quickly as by the omnibuses. There would be nine stations, including the two termini, at intervals of about half a mile. There were about 34 petitioners who were afraid of the injury by vibration when the line began to work; but they would have the best scientific evidence of Mr. Greathead, who was assisted by Sir John Fowler and Sir Benjamin Baker, to show that no such thing need be apprehended. The route followed the great thoroughfare through Oxford-street and Holborn to the Bank. As to the mode of construction, it would be different from the other underground railways of London built some 25 years ago, inasmuch as there would be no disfigurement of the streets, the plan proposed being to take sites for stations on the route, and work underground from those stations, bringing up the material and

Digitized by Google

carting it away without any disturbance of the traffic. A further point of difference here would be that there would be no noise heard above ground. There would be no thundering of trains over an iron-floored bridge. There would be no blow-holes, because they worked by electricity instead of steam. There would be no ventilating shafts, because the tunnel was to be double; and the trains in each of the two tunnels would go in one direction continually, so that they might have too much rather than too little draught. The tunnels were 11ft. in diameter. The mode of construction was to push forward an iron shield, so that the earth was supported as the work was carried on; and it was forced forward by an hydraulic arrangement. The great depth at which the work would be carried on in the London clay precluded all chance of subsidence; the line being constructed on such substratum could not injure any one. Then there were 20 petitioners referring to interference with sewers, with gas and water mains, electric mains, hydraulic apparatus, and so forth. Then the Dean and Chapter of St. Paul's were afraid of that structure coming down; but this scheme would have as much effect upon St. Paul's as the tickling of a tortoise's back with a feather.

Mr. JAMES HENRY GREATHEAD was the first witness called. In examination by Mr. Freeman, he said that he was engineer to the City and Southwark Subway, and was responsible engineer for this scheme. Their work would be done at the rate of 15ft. a day; no blow-holes would be required, as in the case of the Metropolitan Railway. There would be no perceptible vibration above ground. The carriages would be entered from the ends, like tramcars, and they would give greater accommodation in height and width than the Metropolitan carriages. The motive power would be electricity, and the generator for the electric current would be at Queen's-road. The current would be carried by a main conductor throughout the whole length of the two tunnels, with a working conductor placed between the rails. The carriages are about half the weight of those run on the Inner Circle Railway—about 80 tons, as against 165 tons. There were some small subsidences near to the Southwark Subway stations, but those stations were made of brick, and in the present scheme they proposed to build iron stations.

In reply to Mr. Pope, Q.C., witness said that the cost of working by electricity would not be more than by steam.

TUESDAY, April 22nd.

On Tuesday, Mr. GREATHEAD was further cross-examined by several of the petitioners upon the alleged injury done to the property on the route.

Dr. HOPKINSON was the next witness. In examination by Mr. Saunders, Q.C., witness said that the London Electric Supply Corporation proposed to transmit 10,000 volts from the Deptford Station. In the case of electric traction the Board of Trade had sanctioned 600 volts, and they were actually using for that purpose on the City and Southwark Subway about 500 volts.

The Board would not sanction electricity being used as a motive power if there was any danger?—No one could come in contact with it unless they were doing that which they had no business to do. Even if there were an accident and they came in contact with a conductor they would experience no harm. He had himself come in contact with 500 volts without suffering any harm.

By Mr. SAUNDERS, Q.C.: There can be no danger from even touching it at the maximum pressure of 600 volts?—I never heard of anyone being hurt at that pressure.

In further examination witness said that the conductor being underground would not be subject to wet, and the insulation would be very good. For the Central London it was intended to use two locomotives for each train, making them substantially the same type as used on the City and Southwark, only a little heavier and more powerful. Engines had been constructed for the City and Southwark, and a contract entered into at so much per train mile, and it was not to exceed ninepence. It would be a much lighter train than is necessary on an ordinary railway. The generating station for the whole of the Central Railway would be at Queen's-road.

What would be the cost of the necessary machinery and plant for working the line?—The estimate for the generating machinery and conductor and locomotives for the train service every two minutes is £275,000.

WEDNESDAY, April 23rd.

Dr. HOPKINSON was then cross-examined by Mr. Pope.—Speaking with reference to the cost of working of electric traction on the Newry line, which the learned counsel put as 88½ per cent., witness said that that would not be a test of what it could be done for, as the Newry Company were not at all dependent upon the proceeds of their line, which was used for bringing coals and goods to their mills.

The remunerative character of the traffic and the working expenses were matters of estimate?—Yes; but we know it pretty well.

Might there not be improvements introduced in the mode of electrical traction?—I do not see where they are to come from.

Cross-examined by Mr. Vane: Supposing the proposed line had formed a connecting line with the City and Southwark, would there be any difficulty in the whole of the electrical power being sent from Stockwell?—No; but it would be undesirable.

Then you mean that the electrical power could be supplied for 4½ miles, but it cannot be supplied for 7½ miles?—No; but it would be more difficult and involve some extra cost. It could not be done without going to a higher electrical pressure, which would have increased the danger. The cost is increased when it is worked at a higher pressure; but, excepting that question of cost, there would be no engineering difficulty. The extra cost of plant would be somewhere about £100,000, and the extra cost of running would be, perhaps, 3d. or 4d. per train mile. Taking 9d. as the estimated cost per train mile on the Central London, if they worked it from Stockwell on the same pressure it would be 12d. or 13d. per mile.

Working it from Queen's-road, then, you would require about 2,500 horse-power to produce the equal amount of electricity?—For ten trains a day, with a 3½-minute service, for 18 hours per day, it would be about 2,000 horse-power. The coal consumed would be about 2½lb. per horse-power.

Is not 3lb. the right thing?—It can be done easily with 2½lb. It would amount to 38 tons for the whole day.

Supposing an accident happened, and the passengers had to get out and walk to the nearest station, would they sustain a series of shocks, which you have described as disagreeable but not dangerous?—They would not get a shock. They would be told not to touch the rails.

Is not the loss 85 per cent., as proved by experiment?—No experiment could possibly have given the result of only 15 per cent. of the power being useful, and 85 per cent. loss. The people who experimented must not have known anything about it. The loss of electric working was double the loss of steam working; but there were other compensating advantages.

Does not the cost of electrical working increase out of all proportion to the increase of speed?—By no means. You may take it that the cost per ton per mile would differ very little for the speed. The cost of electric working per ton per mile is the same at whatever rate of speed.

Comparing the cost of electricity with the cost of locomotive power by steam, would the cost of nine miles an hour be twice as much upon coal, water, and so on, as working by steam?—In my judgment the cost of running the trains on the Central London would be less than running on the Metropolitan. There would be a lighter train for a greater number of passengers on the Central London.

Supposing an equal power existed, equal weight of train, equal speed and equal distance, would not the cost of electrical power at a speed of nine miles be twice as much as steam power?—No; it would be little more than steam.

You do not agree that if the speed was increased up to 15 miles an hour that then the cost between electricity movement and steam movement is very largely increased?—I do not.

If I suggest that it is four times the cost of the locomotive you would not agree?—Certainly not.

Do you happen to know that these very experiments were tried last February on the Manhattan Railway in New York with the express purpose of obtaining what the cost was by electric power and by locomotive power?—I know that experiments were tried, but I do not know the result.

Do not you know that on the report of the experiments being made the Company decided that they could not adopt electrical power, and they adopted steam power?—I do not know; but that would be the natural result if the figures turned out as you have stated.

By Mr. BIDDER: Will your engines alternately pull and push?—That is the proposal.

Do not you know that pushing a train is in direct contradiction to the directions of the Board of Trade?—I do not.

Do not you know that if the engine is in front and is drawing the train the tendency is to keep it on the rails, but if it is pushing it the tendency is to magnify the departure from the curve?—That is a point a good deal discussed among engineers.

But you pull and do not push the train there?—That is so. But supposing the Board of Trade were to take exception to pushing and pulling, the only inconvenience would be a slight loss of time at the terminals. It is simply introduced to avoid the coupling and uncoupling of the engine, and that is a saving of a minute and a-half.

I suppose I am right in saying that the expenditure of electric power and the cost of locomotion is proportionate to the weight of the train?—Yes. The cost of the City and Southwark is 3½d. per train mile, and the cost of the Central London is 9d. per train mile.

Mr. MATHER, M.P., next gave evidence with reference to his firm's guarantee as to the cost of the City and Southwark line. He said that the cost per train-mile was guaranteed not to exceed 3½d.; that would include the cost of the engine drivers and the maintenance of the generating plant, and the coal and the various items which go to generating the current, but it does not include the drivers on the locomotives. Basing these calculations upon their experience of the City and Southwark, his firm had come to the conclusion that they could, at 9d. per train-mile, provide the whole of the plant for the Central London for £275,000. That is for a two-minute service and 18 hours per day. The estimated weight of the loaded train on the City and Southwark was 30 tons, and for the Central London 80 tons. The £275,000 would include the dynamos necessary for generating the current. The pressure is not to exceed 600 volts.

Sir THOMAS FARRER was next called. He stated that he was a resident in Marylebone, and an Alderman of the County Council. The attitude of the County Council towards this scheme was this:—A few weeks ago the Parliamentary Committee of the County Council laid before that body a report in which a great number of arguments were produced against this scheme; and the effect of that would have been to oppose the whole scheme. An amendment was moved by Mr. Bridgman, and seconded by himself, to the effect that the action of the County Council should be confined to protecting their powers and the other interests of the Council, and he believed the amendment was carried without a division. Last February witness presided over a meeting of ratepayers to protest against the Vestry of Marylebone spending money in opposition to this scheme. The idea of the Vestry was that this underground railway would take people from their shops and send them into the City; but even if that were so that objection should not stand in the way of a great public improvement. In the County Council they were having pressed upon them almost daily the necessity of making improved thoroughfares, and when they

Digitized by Google

made these thoroughfares they were done at great cost to the ratepayers. Now, here was a plan by which it was proposed to make a great thoroughfare from the West End to the centre of London without calling upon the ratepayers to pay one penny. Therefore it was in the interest of the County Council and the ratepayers that such a scheme should be carried out.

Sir JAMES WHITEHEAD was also called in support of the scheme. He was speaking individually, and not as the representative of the Corporation. Notwithstanding the opening of Queen Victoria-street, the traffic in the streets of the City was greater than formerly. He would have been an opponent of this scheme if he had thought that it would do any injury to St. Paul's, Holborn-viaduct, or the City sewers.

The Committee was again adjourned.

THURSDAY, April 24th.

The Committee continued the hearing of the evidence for the promoters of the scheme to-day, and several Inspectors of the City and Metropolitan Police were called to speak with regard to the difficulties they had to contend with in consequence of the present crowded state of the streets of the Metropolis, and stated that in their opinion the present scheme was calculated to relieve the existing congestion. A full report of the evidence will appear in our next issue.

ARTISTIC ELECTRIC LIGHT FITTINGS.

We have recently received from a number of well-known makers of artistic fittings copies of their newly-issued catalogues and price lists, the elaborate character of which gives evidence of the great demand for these fittings. Some of the designs show most clearly to what charming combinations the electric light lends itself. It may safely be said that at no time was it possible to call in the aid of the workers in brass, copper, silver, steel, and other metals to such an extent as it now is to assist in the embellishment and ornamentation of public buildings, mansions, offices, &c. Indeed, the only difficulty which is likely to arise is in making a selection from the great variety at the command of intending purchasers. We propose to call the attention of our readers to some of the more striking designs forwarded to us; and as the catalogues from which they are selected are issued by some of the best-known firms in the kingdom, materials and workmanship leave little room for improvement. Lastly, the moderate cost of most of these fittings is by no means their least attractive feature. A large stock is, in nearly all cases, kept.

MESSRS. EVERED & COMPY. (LIMITED).—In the illustrated catalogue of bright brass, bronzed-brass, copper, and wrought-iron fittings for the electric light issued by this firm, every taste is consulted. No. 504 is a plain strong two-light pendant in bright brass, extremely cheap and serviceable, and the wall fittings on the same sheet may fairly be described as of the "useful" sort, while in the group 721, 726, 728, 732, 739, and 741 will be found a series of neat designs. This description also applies to a succession of sheets, upon which are displayed a large number of wall lights in various metals, all of which are very low in price, and many of them most artistic in design and excellent in workmanship. The remaining sheets are devoted to illustrations of electroliers, many of which possess artistic merits of a high order. These fittings can be seen at the extensive show-rooms of the Company, Holborn Viaduct, E.C., a visit to which will well repay intending purchasers.

MESSRS. HULETT & CO. (LIMITED).—In the catalogue recently issued by this firm are illustrated a large number of brackets, ship and ceiling lights, suspension lights, electroliers, standards, portable stands, mirrors, &c., chiefly in brass, copper, and wrought-iron work. A number of these are very elegantly designed. From the brackets may be selected Nos. 236, 237, 217, 246, 247, 249, 200, and 205. These are chiefly in polished copper and brass. In wrought-iron work, the number of brackets and suspensions illustrated offers a large choice. A number of very ornamental ceiling lights are given, and Nos. 300 and 303 are especially well designed. The catalogue contains a large selection of electroliers, the designs of several of which show much taste. No. 443 is a 5-light wrought-iron electrolier: and No. 408 a 3-light, with projecting arms, both of excellent workmanship and design. Nos. 406 and 415 are very ornamental, the former being a 5-light electrolier with repoussé brass work, each arm projecting 12 inches. Messrs. Hulett invite inspection of their large stock at 55 and 56, High Holborn, W.C.

MESSRS. LAING, WHARTON, AND DOWN.—In this firm's catalogue No. 810 is a charmingly-designed four-light suspension electrolier with reflectors, which is admirably adapted for large hotels, restaurants, mansions, &c. No. 855 is a five-light example of the same class, fitted with opal shades, and of very chaste design. No. 893 is a five-light tall standard suitable for reading and smoking rooms, entrance halls, &c. No. 884 is an eight-light ceiling fitting, with holders in shaped metal, and No. 821 on the same sheet of illustrations is a three-light suspension fitting of neat design and fine workmanship. In No. 876 we have a choice specimen of the metal-workers' art in the form of an eight-light pendant with cut-glass bulbs. The above are only a few specimens, of which the catalogue under review contains more than 100 illustrations, including pendants, suspensions, brackets, reflectors, &c. The firm notify that all the patterns included in the catalogue can be had in their new combinations of steel, bronze and silvered, or red metal and silvered. The above can be seen at Messrs. Laing, Wharton and Down's show-rooms in New Bond-street, London, W.

WINFIELDS (LIMITED).—The catalogue of this firm contains 25 large quarto sheets of engravings of various descriptions of pedestals, table lamps and stands, pendants, brackets, ships' fittings, and hall lamps. Only a small selection of table lamps is given, but the designs are neat. Several illustrations of table stands for electric light are given, many being of elegant design. There are a few examples of combination gas and electric light pendants, but the chief feature of the illustrations is a large number of designs in polished brass and copper of electric light pendants. In these great originality and taste are shown. We direct the particular attention of our readers to Nos. 11614, 11609, 11607, 212, in the list of brackets. Messrs. Winfields' show-rooms on Holborn Viaduct, London, E.C., are well stocked.

WOODHOUSE & RAWSON UNITED (LIMITED).—This Company issue a handsomely bound volume, neatly indexed, of brackets, pillars, hall and vestibule lights, reflectors, suspensions, large, medium, and small electroliers, ceiling fittings, &c. Some of the designs are very handsome, and in particular we may mention amongst the brackets Nos. 9,291, 9,182, 10,382, 9,271, and 9,592. Amongst the hall lights are two elegant specimens, Nos. 10,346 and 10,371. A well-designed suspension light is shown in No. 10,335. Amongst electroliers selection is difficult, as all are of excellent design; but Nos. 9,681, 9,637, 10,244, 10,342, 9,770, 10,334, 10,348, 9,292, 9,270, 9,454, and 9,455 are very ornamental. Of ceiling fittings a well-assorted group is shown. Messrs. Woodhouse and Rawson's catalogue is in sheets of photographs, and is got up in the best possible style. The firm's large new show-rooms, at 88, Queen Victoria-street, E.C., contain a large stock of these fittings.

In dealing with the above catalogues, we have not attempted in any way to exhaust the number of the specially excellent designs which they each and all contain. We must refer our readers to the catalogues themselves for a large selection of all kinds of artistic electric light fittings, both for heavy and light wear. Each of the firms under notice have evidently determined to put before the trade their best work. In each case the catalogues are well printed, and no expense has been spared to assist the trade and their clients in the selection of fittings for all purposes. In addition, we may repeat that perhaps the most important feature of all is that the prices quoted are in most cases very low, taking into account the excellence of design and workmanship.

Several well-known firms have catalogues in the press, which we hope shortly to review.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 11, 1890.

National Fast Telegraphing Tournament.—A good deal of interest was excited here by the National Fast Telegraphing Tournament, which came off in Hardman Hall, on April 10th. The event drew together a large audience of telegraphic experts from various parts of the country, and the hall was crowded from one end to the other. Sounders were distributed along the sides of the hall, so that the entire audience could catch the details of the contest. The test for speed employed was the maximum number of words sent in five minutes, the only restriction being that the sending should be fairly readable. Special prizes were offered for the clearest and most finished operation. The result was a surprise, even to the most expert telegraphers; and the first prize was won with the record of 260 words for five minutes—just 52 words per minute. The winner was a Mr. B. R. Pollock, train despatcher of the New York and New England Railroad; and his record showed by all odds the fastest sending that had ever been witnessed in a telegraph contest up to the present time. The speed, in fact, was so great that many of the audience had great difficulty in following it, although some expert telegraphers could keep up with the pace, and pronounced it reasonably clear. None of the other contestants came very near to this speed, although there were

Digitized by Google

several beautiful exhibitions of distinct sending at a speed of about 240. A special class was provided for ladies, and the winner scored 217 words. It will probably be a long time before the speed reached in this contest is beaten. Every signal sent by any of the operators was recorded on a Morse receiver, and was subsequently reproduced, so that it could be studied in detail by means of a very ingenious repeater operated by the record slips.

The Rumoured Electrical Trust.—The rumoured consolidation between the Thomson-Houston and Edison Companies is now authoritatively denied. The rumour was apparently based upon the fact that the Thomson-Houston Company has increased its capital stock to a little over $12,000,000, and this increase was assumed to mean a proposed combination. In the case of the combination ever occurring it is more likely to take the form of a gigantic trust of a somewhat unofficial character, than a direct union of the companies concerned.

Electrical Execution.—Considerable interest is being excited just now by the approaching execution of murderer Kemmler by electricity. There is apparently no escape for him now; and unless he is pardoned, which is scarcely likely to happen, the merits of electrical execution will have been effectively tested by the end of April. The execution is supposed to be a secret one, except for those having it in charge, and for a coroner and his jury. However, on the coroner's jury will be one representative of the New York Associated Press, and one of the United Press, consequently it is not altogether improbable that the public will be treated to an account of the details of the execution, although the publishing of such an account is prohibited by law. It is altogether probable, however, that no very violent legal proceeding would follow the publication by the Associated Press. The execution will be superintended by Mr. Harold P. Brown, who provided the apparatus for the purpose.

Edison Alternate-Current Patents.—A rumour is floating about town that the Edison Company is more interested in alternating currents than might be supposed. It is, of course, well known that the Company possesses certain alternating current patents, but it is more than suggested that these patents will now be withdrawn from the pigeon-holes in which they have reposed for the last few years, and may appear in a more public fashion.

New Vacuum Pump for Incandescent Lamps.—A report comes from Boston of a trial of a new pump for exhausting incandescent lamps. The details of the apparatus have not been made public as yet, but it is not a mercury pump; it is rather an improved air pump of such large size that it can exhaust a large number of lamps with great rapidity, the vacuum obtained being better than ·001. Some of the experiments tried on a large group of lamps were very striking, the current being turned on the lamps in 22 seconds after the pump was started, showing a good vacuum. The pump was operated by steam power. Its cylinders are three in number.

The Molecular Telephone.—A vigorous effort is being made to push a highly improved form of acoustic telephone, called by its inventor a molecular telephone. The Company has formidable financial backing, and are expected to establish several central stations shortly. The instrument used speaks very clearly and distinctly, and operates with considerable success up to a distance of two miles. Whether it will be a formidable competitor of the Bell telephone for small central stations remains to be seen, but for private lines such an instrument is very effective.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

April 23, 1890.

MM. Mildé et Fils have obtained the concession of a sector bounded on the north and west by the line of the fortifications, from the Porte St. Cloud to the Porte d'Asnières, on the south by the Seine, and on the north and east by the Boulevard Malesherbes, the Rue Royale, and the Place de la Concorde. The length of street to be canalised amounts to 37 kilometres, and the proposed system of distribution will involve a large use of accumulators. Both the Compagnie Continentale Edison and the Société de la Transmission de la Force have obtained extensions of their areas. Trials are shortly to be made at the Municipal Station at the Halles with coke fuel.

M. Lyon-Alemand has laid a proposition before the Conseil Municipal for the erection of a municipal central lighting station at Bercy. The 100,000fr. recently voted by the Conseil Municipal will be spent on the electric lighting of the Rue Auber and the Rue des Halles by incandescents, and of the Quai Valmy, the Quai de Jemappes, the Avenue de Clichy, and the Rue des Apennins by arcs.

The idea of using the upper stories of the Bourse as a central telephonic exchange has been abandoned, and it is now proposed to erect a three-storied building opposite the new General Post Office. There will be three switchboards, each capable of accommodating 6,000 subscribers. It is hoped that the new exchange will be ready by next year.

The Société Française d'Accumulateurs Électriques have brought an action against the makers of the Pollak accumulator. The question has been relegated to a committee of experts.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *April* 21, 1890.

The Testing Department for Electricity of the Imperial Royal Technological Museum has published its report for 1889, which shows that every year it is being made more use of. The principal work has been the testing of conductivity of various sorts of wire, their breaking strain, &c., also the testing of the insulation of cables. This has been principally in connection with the electric lighting of the Volkstheater. In this matter they practically acted as consulting engineers for the institution. They also tested and reported on the electric light installation at the Western Railway Station, and tested and stamped the electric meters in the Court Theatres.

The telephonic development in Austria during 1889 has been very considerable. Apart from the numerous small exchanges opened by the Government in the smaller towns, the existing exchanges have developed rapidly. In Vienna the number of subscribers has increased to 3,000, and the demand is so large that the Vienna Company are enlarging their central station to one of 5,000-subscriber capacity, and are raising a large amount of new capital to run the necessary cables. Even now Vienna has probably the largest number of subscribers in Europe concentrated in *one* exchange. This exchange is beautifully fitted up with a multiple switchboard of the company's own design, made by M. Schäffler, of Vienna, and the service is rapid and good.

In Prag, one of the towns worked by the Telephone Company of Austria, the exchange is fitted up in the same way as the Vienna exchange, with their multiple board for single and double wires. During 1889 the development of the provincial exchanges worked by the above-mentioned English company has also been very satisfactorily. The number of subscribers, exchange and private, has increased to 755 in Prag, 538 in Trieste, 428 in Lemberg, 440 in Graz, 114 in Czernowitz, 152 in Pilsen, 364 in Reichenberg, 160 in Brilitz—total, 2,951, with 6,120 kilometres of wire. In 1889 145,667 telegrams were transmitted by telephone through the Prag exchange.

CORRESPONDENCE.

ALTERNATE v. CONTINUOUS CURRENTS IN RELATION TO THE HUMAN BODY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The experiments of Dr. Harries and Mr. Newman Lawrence, an account of which was given in your issue of April 4th, are certainly very interesting; but the interpretation given to them and the conclusions arrived at are hardly in accordance with modern views and with the teachings of practical experience. It is out of date now to doubt the general correctness of Ohm's law; and, as a consequence, the "resistance" of a body to electric currents must be the same, whether they be continuous or alternating. The apparent discrepancies found were generally mainly due to the effects of self-induction not being taken duly into consideration, and also

Digitized by Google

to comparing with one another results obtained under different conditions.

In the experiments above referred to the human body was balanced in a Wheatstone bridge by coils of wire till a telephone was brought to silence; and it was found that about one-eighth of the resistance necessary to arrive at the balance with continuous currents was necessary with the secondary currents of an induction coil for silencing the telephone. Now this proved nothing else but that the self-induction effect of the resistance coils used was, under the circumstances of the experiments, several times larger than the ohmic resistance of the same; and this is nothing extraordinary with currents varying as suddenly in intensity as these obtained from a Ruhmkorff coil. Part of the difference found with alternate currents as against continuous currents is also accounted for by the great difference in the tensions of the current used. The right way to ascertain the true resistance of the human body with alternate currents would be to submit it to the action of a current of known volts (measured by a Cardew voltmeter) and to measure the intensity of the current traversing the human body. The resistance found with this method would be the same as that measured under similar circumstances with continuous currents. Owing to the difficulty in measuring alternate currents of only a few milliamperes this plan has, to my knowledge, not yet been successfully tried.

A more feasible plan is to arrange a Wheatstone bridge with resistances as free from self-induction as possible. To this end I used for three sides of the same series of from five to ten 10 candle-power incandescence lamps, the fourth side being represented by one of my assistants grasping tightly two stout copper handles. A closer adjustment can be easily performed by exchanging some of the lamps with others of 16 candle-power. With 15 volts alternate current of 50 complete periods per second silence of the telephone in the bridge indicated between 4,000 and 5,000 ohms for the human body; the same values limited the resistance when putting on 30 volts continuous current with a sensitive Deprez-d'Arsonval galvanometer in the bridge. How misleading the comparison with the resistance measured under somewhat different circumstances would be, is illustrated by the same assistant with the same handles being found equal to about 15,000 ohms immediately before and after this experiment when measured with a large Elliot bridge and three volts only.

My seven years' experience with alternate currents tends to show what has been also pointed out by some of the speakers in the discussion, namely, that about double the tension of continuous current can be withstood with about the same amount of discomfort as would be the case with alternate currents.

I hope with this not to encroach upon the valuable space of your esteemed paper.—Yours, &c., OTTO T. BLÁTHY.

Budapest, April 16, 1890.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I desire to say a word or two in reply to the letter of Mr. Henry M. Sayers, on the above subject, in your last issue.

After quoting from the Paper of my colleague and myself, to the effect that to produce muscular fixation with alternating currents a voltage of 6·26 is sufficient (*under the conditions we named, of resistance, position of contact, area of contact, &c.*), Mr. Sayers goes on to say, "Ten times this ought to produce death surely;" and then adds, "This result is, of course, simply absurd in the light of everyday experience." No doubt it is "absurd;" but this *conclusion is that of Mr. Sayers*, and is not in any way justified by what we said in the Paper or after it. It would be just about as reasonable to say that because a certain dose of medicine taken by one individual, *under certain conditions*, produces unpleasant consequences, therefore ten times that dose will kill that same or any other individual *under any conditions*.

In our Paper we distinctly state, in reference to the minimum current which will destroy human life, "We feel sure that no hard-and-fast lines can be laid down on the subject. *Individual resistance and individual sensitiveness vary so much and so unexpectedly* that a current which might be taken with impunity by one person might be more than enough to kill another."

Your correspondent also considers our measurements of resistance open to objection, and says, "Probably the results given by measurements made with alternating current would be different." This form of objection is decidedly amusing, because *we did use alternating currents* for the measurements, as he will find clearly stated if he will take the trouble to look at the Paper again.

I will not presume to combat the fatherly rebuke which Mr. Sayers administers to the Council of the Institution of Electrical Engineers No doubt it will be severely felt by the members of that erring body.

It only remains for me to remind your correspondent that, "in the light of everyday experience," it is advisable—or, at least, it is fair—to read carefully and quote accurately any Paper it is desired to criticise in a public journal.—Yours, &c.

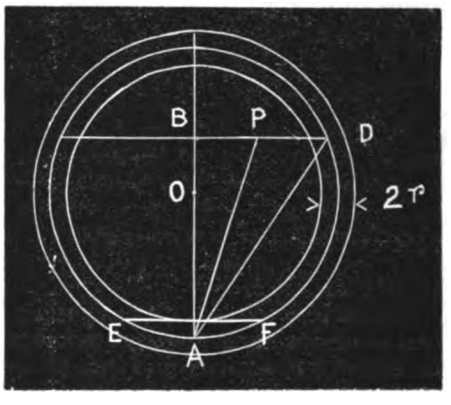
H. NEWMAN LAWRENCE.

The Institute of Medical Electricity,
24A, Regent-street, S.W.

THE CO-EFFICIENT OF SELF-INDUCTION OF A SINGLE CIRCULAR LOOP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As far as I am aware, the self-induction co-efficient of one single circular loop of wire has up to now been developed only in an approximate form; the following deduction resulting into the exact co-efficient represented by a closed expression will therefore be of some interest.



Let us put

$O A = R$ $\quad$ $A B = x$

$A P = \rho$ $\quad$ $B P = y$

Angle $B A P = a$ $\quad$ Angle $B A D = a'$

τ R, radius of wire.

$d s$, element of wire.

The magnetic force at P due to the element $d s$ is given by

$$\frac{i \cdot d s}{\rho^2} \cos a.$$

The total induction through the circle of radius R (no magnetic material being supposed in the field) is therefore for the unit current,

$$L = \iiint \frac{i \cdot \cos a}{\rho^2} d x \cdot d y \cdot d s,$$

the integrations extending over the area and round the circumference of circle R. Now we have $d y \cdot \cos a = \rho \cdot d a$ and $\rho \cdot \cos a = x$, therefore

$$L = 2 R \pi \int \int_{-a'}^{+a'} \frac{i \cdot \cos a}{x} d x \cdot d a = 4 R \pi \int i \cdot \sin a' \frac{d x}{x}.$$

But $$\sin a' = \sqrt{1 - \frac{x}{2 R}};$$

then $$L = 4 R \pi \int \frac{i d x}{x} \sqrt{1 - \frac{x}{2 R}}.$$

For the space above E F the current i is equal to the total cur-

Digitized by Google

rent in the wire, that is unity. But for the segment between E F and the axis of the wire we have $\frac{x^2}{i} = r^2$. Therefore,

$$L = 4\,R\,\pi\left[\int_0^r \frac{x\,.\,dx}{r^2}\sqrt{1-\frac{x}{2\,R}} + \int_r^{2R}\frac{dx}{x}\sqrt{1-\frac{x}{2\,R}}\right].$$

Integrating and reducing to the simplest form we get

$$L = 4\,R\,\pi\left\{\text{log. nat.}\,\frac{4\,R - r + \sqrt{16\,R^2 - 8\,R\,r}}{r} + \frac{16\,R^2}{15\,r^2} - \left(\frac{16\,R^2}{15\,r^2} + \frac{4\,R}{15\,r} + \frac{8}{5}\right)\sqrt{1-\frac{r}{2\,R}}\right\}$$

This is the exact total induction through circle of radius R by unit current in wire of radius r forming said circle. Developing in series we have, as an approximate expression,

$$L = 4\,R\,\pi\left[0{\cdot}57944 + \text{log. nat.}\,\frac{R}{r} - \frac{2\,r}{R} - \frac{r^2}{24\,R^2} - \frac{r^3}{48\,R^3} - \ .\ .\right].$$

Yours, &c.,

Budapest: April 16, 1890. OTTO T. BLÁTHY.

STREET LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A paragraph has recently appeared in the columns of the daily press as to the lighting of Chelmsford by electricity, in which it is stated that this is "the first town in the country to be lighted throughout by electricity." My Directors would be obliged if you would allow me to correct this statement. The town of Weybridge, in Surrey, is lighted by us throughout by electricity; and as this installation was started on March 1, 1890, Weybridge can certainly claim precedence over Chelmsford. Nearly the whole of Waterford has been lighted by us for nearly three years, and all the principal streets of Taunton (visited last week by an official deputation from the city of London) have been lighted on our Thomson-Houston System for more than three years.—Yours, &c.,

W. MARTINDALE, Secretary.

The Laing, Wharton, and Down Construction Syndicate,
82A, New Bond-street, London, W., April 18, 1890.

WORD-COINING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It does seem strange, considering the progress made in electrical appliances in recent years, that no single comprehensive word has yet been adopted meaning, briefly, motion having electricity as the motive power. May I suggest the following simple yet concise word, conveying a meaning peculiarly its own? That is, the word "motel"—*mot-el* being an abbreviation of the two words motion and electricity, and meaning "to move, or impart motion to, anything using electricity as the moving force." It appears to me a very simple and convenient word, and one that might readily be adapted to the various forms of speech similar to the word "propel." For instance, in the case of the words "electric motor" the word "motellor" may be substituted. The word "motel" being so simple would, if adopted, soon prove itself convenient to the English-speaking community at large. Hoping it may do so, I remain, Yours, &c., "NAVIS."

Devonport.

DYNAMO AND MOTOR DESIGN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue Mr. W. B. Sayers takes exception to part of my letter published on the 11th inst.; and although I have no desire to be drawn into a newspaper controversy on the subject, I should like to be allowed to reply to his exceptions.

First, as regards the sentence "Laminating the cores has the effect of reducing the divergence," of which he complains, I would point out that what he said at the meeting was "If the core of the armature is well divided and insulated, so as to make the Foucault currents very feeble, the difference between the dynamo and the motor is reduced to a minimum." Your readers may judge whether my statement is or is not a substantially correct version of what he said. He has, in correcting the reporter's transcript, inserted the words, "and non-sparking conditions are fulfilled as regards position of brushes, &c.," after "feeble;" but these did not form part of his remarks.

With reference to the re-written copy, I admit that the *corrected* transcript is practically the same, but the corrections are somewhat numerous and lengthy; in fact, the corrections and the inserted matter amount to about one-tenth of the whole transcript. If the "explanatory note" be included, then the proportion would be about one-quarter.

With the latter part of Mr. Sayers' letter it is not in my province to deal.—Yours, &c.,

THE WRITER OF THE ABSTRACT.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty will, on an early date, sell by auction, at the High and Low Mills Forge and Chain Works, Gateshead-on-Tyne, the valuable steel and iron working plant, machinery, and buildings until recently in the occupation of Messrs. Hawks, Crawshay, and Sons (who are retiring from business). Further particulars are given on page xvii.

THE GREAT TOWER IN LONDON.—An advertisement on page xvii. announces that, by permission of the Master and Wardens of the Drapers' Company, an Exhibition of the drawings, plans, and designs submitted in this competition will be held on May 1st, 2nd, 5th, 6th, 7th, 8th, and 9th, free of charge.

METROPOLITAN ASYLUMS BOARD.—The Board has accepted the tender of Mr. C. Bull (Stoke Newington) to supply and fit electric bells from the wards of the Eastern Hospital at a cost of £47. 10s., and to maintain the system efficiently for £8 per annum.

MESSRS. D. HULETT AND CO.—This firm have just issued a very comprehensive catalogue of electric lighting plant and material manufactured and supplied by them. The book is well printed, and contains illustrations, descriptions, and prices of a large quantity of heavy plant, and of measuring instruments, switchboards, switches, safety cut-outs (double and single), roses and wall-blocks, distributing switches and fuse boards, arc lamps and lanterns, carbons, incandescent lamps, lamp-holders, &c. &c. The catalogue also contains some really first-class illustrations of fancy lamp shades, glass globes and shades, &c. &c., and concludes with tables of various descriptions of electric light wires and cables.

THE UNITED ASBESTOS COMPANY (LIMITED).—This Company have recently opened an additional branch house at Provident-buildings, Clare-street, Bristol. The Company now have branch houses at Glasgow, Newcastle-on-Tyne, Liverpool, Cardiff, Bristol, Paris, and St. Petersburg.

ELECTRIC PUMPS.—Messrs. Shippey Bros. (Limited) have on private view a small American high-speed triple-action electric pump, which is being worked by a ¼ horse-power Crocker-Wheeler electric motor, which will pump 1,000 gallons of water per day to a height of 100ft., at a cost of less than 6d. per day for current. Special pumps are being constructed, with automatic regulators, for working on arc circuits of 3, 6½, and 10 amperes. It can also be worked by battery power, for use in country districts, at an esti mated cost of about 1s. per day for chemicals consumed.

OZONISED PRODUCTS.—Mr. Ernst Fahrig, of St. Helen's Ozone Works, Plaistow, is exhibiting a collection of samples of ozonised products at the Permanent Chemical Exhibition in Manchester.

THE EXEMPTION OF MACHINERY FROM RATING.—We are asked to thank the many friends of the movement undertaken by the National Society for the Exemption of Machinery from Rating, for the assistance they have lent. As our readers are probably aware, this movement was brought to a successful issue on the 23rd instant. Machinery users certainly owe their thanks to Mr. Winterbotham, M.P., and the other gentlemen who supported him in Parliament, and the large number of persons who have worked hard to get the injustice complained of redressed. Any of our readers who are interested in this subject can obtain information and assistance from the Society, whose offices are at 22, Buckingham-street, Adelphi, London, W.C.

3,024. Lake (Parkhurst). Electric motors. (Price 11d.)

LEGAL INTELLIGENCE.

Phillips Brothers v. Crompton and Co. (Limited).

In the Divisional Court on Friday last, before Mr. Baron Huddleston and Mr. Justice Grantham, an appeal was heard from a decision by Mr. Justice Lawrance, in Chambers, in a dispute between the above-named firms.

In June, 1889, Messrs. Phillips supplied to the order of Crompton and Co. (Limited) a quantity of electric lighting wire, called "C" wire, to be used in lighting Chelmsford with electricity. Crompton and Co. (Limited) paid the cost, over £1,200, less £54. 17s., and further received some insulated wire to the value of £1,350. In January Crompton and Co. (Limited) issued a writ against Messrs. Phillips for damages, alleging that the "C" wire was not equal to warranty, and in February Messrs. Phillips issued a writ against Crompton and Co. (Limited) for the balance above named, and the cost of the insulated wire, total £1,405. 18s. 8d., applying for judgment under Order 14. Crompton and Co. (Limited) thereupon applied for the consolidation of the actions, and that Messrs. Phillips's claim should be set up as a counter-claim to their claim for damages for breach of warranty. The Master at Chambers refused to consolidate the actions, and gave judgment for the amount named, staying execution until the damage action was tried. The order was appealed against; Messrs. Phillips asking for payment under their judgment, and Crompton and Co. (Limited) for the consolidation of the actions. Mr. Justice Lawrance thereupon directed that upon Crompton and Co. (Limited) bringing £500 into Court within seven days the order of the Master should be set aside, and the actions consolidated, the defendants having liberty to defend; otherwise the Master's order to stand. The money had not been paid into Court, and the application now was by Messrs. Phillips that the order of Mr. Justice Lawrance be valid, and by Crompton and Co. (Limited) that the actions be consolidated and untrammeled by the order to pay £500 into Court.

Their Lordships decided that the actions should be consolidated, costs to be costs in the cause.

COMPANIES' MEETINGS & REPORTS.

The Eastern Extension, Australasia, and China Telegraph Company (Limited).

The thirty-third ordinary general meeting of this Company was held on Wednesday, at Winchester House, Old Broad-street, Sir John Pender presiding.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting, and the minutes of the thirty-second ordinary general meeting, held on October 23, 1889, which were confirmed and signed by the Chairman as correct.

The report of the Directors was taken as read.

The CHAIRMAN: I think I may safely congratulate you upon the report, which I think you will regard as eminently satisfactory (hear, hear). Before, however, asking you to approve of it, I shall, as usual, go over some of the figures in the report, and give you, as I have done on previous occasions, some idea of what we have been doing in the past six months, and what we may possibly be doing in the future. The gross receipts for the half year amounted to £264,103, against £238,854 for the corresponding period of 1888, showing an increase of £25,249. The working expenses have been £73,498, against £71,519 for the corresponding period of 1888, showing an increase of £1,979, which is caused by cable repairs being rather heavier last year than in 1888, and the opening of our new station at Roebuck Bay, Western Australia. The net revenue has amounted to £144,758, against £118,198 for the corresponding period of last year, showing an increase of £26,560 (applause). Comparing the figures for the whole year, the results are as follows:—The gross receipts in 1889 were £520.860, against £478.780 in 1883, or an increase of £42,080. The working expenses in 1889 were £147,271, against £140,816 in 1888, or an increase of £6,455, leaving a net increase of revenue for the past year of £35,625, or nearly 1½ per cent. on the share capital (applause). The usual interim dividends have been distributed during the past year, making, with the dividend proposed to be paid to-morrow, a total dividend of 5 per cent. for the year. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1889, against 6½ per cent. paid in 1888 (applause). The balance of £58,498 has been carried to the general reserve fund, which now stands at £710,113, made up as follows:—Amount of fund at the end of 1888 was £690,454; to which must be added, interest received on investments during 1889, £22,603; surplus profit resulting from revaluation of spare cable and stores in hand, £23,114; and balance transferred from last year's revenue, £58,494; making a total of £794,665; less cost of partial renewals of Hong Kong-Saigon cable, £15,441; and the further expenditure to date on account of the Western Australian cable, £69,112, thus leaving a balance to the credit of the general reserve fund, as already stated, of £710,113. With regard to the revaluation of stores the practice has been to charge the cost of every repair with the full value of the cable and stores used, and any cable recovered in the operation of repair has always been taken into stock at the lowest possible valuation. Much of this cable has, after overhauling and reserving, proved to be of first-class value, and has been used instead of new cable in subsequent repairs when again the repair account has been charged at a rather high rate, so as to be on the safe side. It has been in the knowledge of the Board that the stores and cable in hand were by this means worth more than the book value, and directions were therefore given that an exact revaluation of these assets should be made. On this being done, a surplus value of £23,114. 13s. 4d. was proved to exist, and the Directors consequently passed this amount to the credit of the reserve fund as previously explained. The net result, therefore, of the past year's working is that the general reserve fund has been increased by nearly £20,000, and £88,000 have been provided from revenue towards the payment of the cost of the Western Australian cable, and the partial renewals of the Hong Kong-Saigon cable, besides paying 7 per cent. to the shareholders (applause). As stated in the printed report, further drawings of the Company's Five per Cent. Debentures have taken place since the close of the year, which, when paid off will entirely extinguish the Five per Cent. (1880 issue), and reduce the Australian Government subsidy issue to £386,500, the original capital having been £640,000. The saving by the first operation will be £5,000 a year. The £320,000 of Six per Cent. Debentures maturing in February, 1891, will be paid off when due by the issue of Debenture Stock or Debentures at a lower rate of interest to be decided by the Board later on. A saving on this account will also be effected, amounting, I hope, to about £6,000 a year. I refer to this now because at the last meeting something was said about these Debentures, and as there is a year still before they mature, I think it right to say that we intend to deal with them on such terms as will, I hope, be satisfactory to the holders of them, and at the same time effect a considerable saving to the Company. The subsidy arrangement with the Government of the Straits Settlements in respect of the Malacca-Singapore-Penang connection terminating last August, and the traffic with Malacca not having sufficiently developed to enable the Company to dispense entirely with assistance from the Government, negotiations were entered into for the renewal of the subsidy, with the result that the Straits Settlements have agreed to give the Company £400 per annum for an additional five years. We consider that satisfactory, because the traffic, though slow, is growing; and from what we know of mining operations going on in that quarter, I look to the traffic being by-and-by very considerable (hear, hear). With regard to the cables generally, all the Company's extensive system is now in good working order (applause); but during the past half-year we have had a good many cables interrupted, and had it not been for the duplicate lines the traffic would have been seriously affected. As it was, New Zealand was entirely cut off from telegraphic communication with the rest of the world for some twelve days, to the great inconvenience of the telegraphing public and the Governments. Under these circumstances, and with a view to preventing, as far as possible, further inconvenience, your Directors determined to duplicate the communication between Sydney and New Zealand without delay; and, with the approval of the Governments of New Zealand and New South Wales, the cable, 1,365 nautical miles in length, has been manufactured and despatched, and is now being laid. Ten days hence I hope that we shall learn that the cable is laid. We have received a telegram from our agent at Sydney, reporting that it is "calm and fine at Sydney and Nelson," so that we anticipate no difficulty in carrying out the work promptly and satisfactorily. I may mention in passing that, as stated at previous meetings, we have had a great deal of controversy with the New Zealand Government in the past. We have come to learn this much now, that a single cable is very uncertain; and so much trust is put in business being conducted by telegraphy, that, unless a continuous system is secured our traffic would not increase as it has done. We have, therefore, guarded ourselves in every way by duplicating wherever it is possible to do so with anything like a show of profit. In regard to the duplication of the New Zealand cable there is a great deal of traffic between New Zealand and

Digitized by Google

Australia, and an increasing traffic between New Zealand and Europe. We therefore did not hesitate for a moment to go to this expense so as to secure that traffic and make the system beneficial and secure for the public (hear, hear). A contract has also been entered into with the Telegraph Construction and Maintenance Company for the renewal of a considerable portion of our important main section between Madras and Penang, at a cost of £102,000. This cable passes over very bad ground in the vicinity of the Nicobar Islands, and interruptions have consequently been very frequent, and at times costly. In 1876 it was broken down for nearly eight months, and since 1880 it has generally been interrupted once or twice every year. Last autumn it was twice interrupted; on the second occasion within a few days of the repair of the alternative cable between Rangoon and Penang. Consequently, we had a narrow escape of a total interruption of the traffic between India and the Far East; and, as this might occur during the south-west monsoon, when it would probably be impossible to effect repairs for at least six months, the Board decided to lose no further time in cutting out the weak portion of the line by laying 650 miles of new cable, from Penang to a point west of the Nicobars. The cable has been manufactured and shipped, and the renewal is expected to be completed next month. The new cable will be laid to the south of the existing line, where we have satisfied ourselves, by special soundings taken by the Company's steamers, that a favourable bottom exists. It will also have a much larger core than the existing line, so that the carrying capacity of the cable, when the remainder is renewed, will be greatly increased. During the last six months, therefore, we have not been idle. We have been spending a great deal of money, but I am perfectly satisfied we have been fortifying ourselves and strengthening the Company. At the same time, we have not saddled capital with the outlay. We think that the policy of paying a steady moderate dividend—a handsome dividend it is in these times—and also fortifying ourselves and placing the business on such a sound footing as to secure that dividend, is one that every shareholder will endorse (hear, hear, and applause). Another International Telegraph Conference will be held in Paris in the course of next month. These Conferences, as you know, are held every five years. I have previously told you that the object of these Conferences on the part of the Governments owning the land lines with their long purses, and who are not responsible to a body of shareholders as we are to you, is to get the tariffs reduced. It is a very remarkable fact that nearly all the Governments of Europe are working their telegraph systems at a loss. I do not think you would be satisfied with me and my colleagues if we came before you every six months, and instead of announcing a good dividend as we do to-day, stated that the balance was on the wrong side. At these Conferences, I may say, however, that we have found on the part of the representatives of the different Governments of Europe a fair desire to meet the cable companies and to admit that the cables do their work quicker and even better than the land systems, and that we are entitled to something more in the way of tariff than the land lines charge; but when they tell us that we are to charge this something more, and that they will charge a lower rate, it is a very nice way of getting hold of our traffic. We must be in a position to do the work, not only better than our neighbours, but as cheaply as they do it, otherwise the traffic will drift away from us. We have no voting power at these Conferences. It is our moral influence that gives us the power we possess; and it requires not merely daily, but hourly, attention there to protect your interests. You may depend upon it that they will not be neglected by us in the coming Conference (applause). At the last Conference we carefully considered our tariffs, and reduced the tariff to Australia from 10s. 8d. to 9s. 4d. The first year we sustained a heavy loss, and the second year we did better, and, as I have stated at previous meetings, we have since entirely made up the loss by this reduction (hear, hear). Whenever we can see that by a reduction of tariff we are going to increase our traffic and benefit our shareholders by enlisting a greater support from the telegraphing public, we shall always be ready to take a broad view, and deal with the matter in that spirit. That will be our policy at the coming Conference (applause). At the same time I am hopeful that we shall not be required to make any great sacrifice. There is a great deal of talk abroad about reduced tariffs and what telegraph companies ought to do; but when I look into the statements, I can only come to the conclusion that their authors do not know anything at all about the matter. As a rule I am very much against answering any statements that appear in newspapers. Newspapers have to produce a revenue to make them pay, and by writing fiction when they are without facts, it may pay them better than if they resorted to truth. I therefore accept with considerable reserve many of the statements which appear in the press; but when a statement is made that we ought to carry telegrams from England to Australia for 1s. a word it makes me think that ignorance is going too far; and as the tendency of the public is to believe anything that will apparently further their interests it is necessary that we should show that those who make such a statement have either deceived themselves, or are trying to deceive the public. (Hear, hear.) I therefore venture to trouble you with a few figures on the subject. The actual cable distance to Port Darwin, where the telegrams are handed over to the South Australian Government for transmission to Adelaide and other parts of Australia is nearly 12,000 nautical miles; and the out-payments alone, without giving any return to the Eastern Extension Company for its large system, amount to 4s. 10d. per word. Consequently, it would be very clever for any one to establish a system at 1s. a word, when, before receiving any profit himself, he would have to pay out 4s. 10d. This shows how absurd such a statement is. I shall take you into our confidence and give you the whole of the details, and show how this 4s. 10d. a word is made up: Germany, Russia, and the Indo-European Company receive 1s. 5d.; Persia, 7d.; Persian Gulf Government department, 11d.; India, 7½d.; Java, 1½d.; South Australian Government, 1s. 2d., making a total of 4s. 10d. Consequently, as the actual outpayments are nearly five times as great as the tariff advocated, and the Eastern Extension Company must receive some remuneration for their part of the work, it is obvious that the most elementary principles of the question have not been appreciated or understood. The statement that, "With reduced rates Sir John Pender thinks the Imperial telegraphs, taken as a whole, would yield a profit of a million a year," was equally incorrect and misleading. The only reference I have publicly made to the subject was at the Colonial Conference in 1887, when I stated that if the Imperial Government guaranteed the cables of the Eastern, Eastern Extension, Indo-European, and South African Companies at the then existing market value, and with the existing tariffs, they would make a profit of something like a quarter of a million. This principle would, of course, involve a lower rate of interest to the shareholders; but, on the other hand, a Government guarantee would greatly improve the position and value of the property in the market (hear, hear). So far, however, the suggestion has not had any practical result. Some two or three years ago, speaking of this tariff system and our connection with the Colonies, I stated that if we could get a Government guarantee it would very much enhance the value of our property, that we would be satisfied with a lower dividend, seeing that it was a Government guaranteed dividend; and we put before the Australian Colonies the statement that if they would guarantee the present income that we receive, they might make the tariff what they pleased. I believe the question has been very much discussed, and that it is considered a fair proposal by the Australians. They say the increased traffic would be so large that the Companies ought to take the responsibility on themselves. I say no; and have told them that, if it is to benefit them so largely and they are so satisfied of a cent. per cent. increase in the traffic, we are quite prepared to take 25 per cent. of the risk, but that the other 75 per cent. ought to be taken by the Colonies. I will give you some other figures, because figures are stiff things to deal with when they are accurate and intended to form the basis of argument in the future. We offered, as I say, to accept one-fourth of the risk; and if the reduced tariff of 4s. a word, instead of 9s. 4d., increased the traffic by 100 per cent., as predicted by some colonists, the amount of guarantee the Governments would have to make up would be quite nominal, namely, £12,750 per annum, which, spread over all the Colonies, would mean a payment of only—£3,731 by Victoria, £3,727 by New South Wales, £1,164 by South Australia, £147 by Western Australia, £2,192 by New Zealand, £1,279 by Queensland, and £510 by Tasmania; making a total of £12,750. Now, gentlemen, with such an insignificant sum demanded from the Colonies, I think our proposal to reduce the tariff from 9s. 4d. to 4s. fully meets the case (hear, hear), and if the colonists are not sufficiently alive to appreciate the great benefits which they would derive from it, we are not to blame. I believe, however, that it is a matter that is rather delayed than abandoned. I should not be at all adverse to coming to an understanding which would improve the value of our property and give additional security to the dividend (applause). With these remarks, ladies and gentlemen, I beg to move:—

"That the Report and Accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 4s. per share, both free of income tax, payable on the 24th inst., making with the previous distributions a total payment of 7 per cent. for the year 1889."

Mr. F. A. BEVAN seconded the resolution.

The CHAIRMAN invited discussion in the usual way; but no shareholder rising to address the meeting, he at once put the motion, which was carried unanimously. Continuing, he proposed the re-election as a Director of Mr. C. W. Earle.

The Most Hon. the MARQUIS OF TWEEDDALE seconded the motion, which was carried unanimously.

The CHAIRMAN then proposed, and Mr. EARLE seconded, the re-election to his seat at the Board of Sir Thomas Fairbairn, Bart., which was also carried unanimously.

The retiring auditors, Mr. Henry Dever and Messrs. Welton, Jones and Company, were also re-elected for the ensuing year, at a remuneration of £100 each.

Mr. BLUNDELL then proposed a vote of thanks to the Chairman and Directors for their services in the past year, remarking that it was quite clear from the Chairman's statement that the Board's duties were no sinecure (hear, hear). There were probably few undertakings which demanded from the Directors such varied talents and so much attention as a Telegraph Company required.

The motion was seconded, and carried unanimously.

The CHAIRMAN, in acknowledging the vote of thanks, said: Gentlemen, there is no reward more precious to myself and co-Directors than your approval of our policy and our general conduct of the Company's affairs. This is a big concern, and is growing every day. It requires a great deal of attention, sound judgment, and sometimes good temper. I have never been more satisfied with the working of our submarine system than I am at this moment. In the earlier days when I addressed these meetings, I used to say that we had a deal to learn as to repairing cables when they were broken. I have known the time when the breaking of a cable caused me many sleepless nights; but I do not miss my rest now at such an occurrence, because we know where to find the fault, and we can repair it. I look on this property, therefore, as a sound property—as one that is commanding the confidence of the public, and, more than that, as one that the world and the Governments of the world cannot for a moment dispense with. We are, therefore, a great public necessity, which, in our hands, I hope will always be guided and piloted with such a degree of moderation and judgment as will command not only the approval of our shareholders, who are first entitled to our consideration, but also the support and approval of the Governments, who are watching us very closely, and of the general telegraphing public. As long as we do our work well, I doubt very much if anyone can attack us at any point whatever (hear, hear, and applause).

The proceedings then terminated.

Reuter's Telegram Company (Limited).

The twenty-sixth ordinary general meeting of the shareholders of this Company was held on Wednesday last at the offices of the Company, 24, Old Jewry; Admiral the Right Hon. Sir John C. D. Hay, Bart., K.C.B., presiding.

The SECRETARY (Mr. W. F. Bradshaw) read the notice convening the meeting.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: In moving the adoption of the report, I have to congratulate the shareholders that, on this occasion, the twenty-fifth anniversary meeting of the Company, the Directors have to present a favourable statement. At our last meeting we had rather poor results to show for the year 1888, owing to causes which were then indicated. The year 1889, though not devoid of important events, entailing considerable expense for telegrams, has been, comparatively, a quiet one. There have been none of those little wars which drain our coffers without our deriving extra contributions from subscribers. The quieter state of political affairs has been accompanied by great prosperity in most countries, and the company's revenue has, in consequence, been swelled by extra sources of income. In a business like ours it is always unwise to disclose our affairs too minutely for the advantage of active competitors, whom we have to face in many quarters; and we know our shareholders always appreciate our reticence. We must warn the shareholders that a check to trade means a restriction of commercial telegrams and subscriptions, so that the favourable figures we now submit to you must not be considered as outside the influence of trade fluctuations as well as political affairs. For this reason the Board have thought it prudent to replace two-thirds of the amount which was taken from the reserve fund to make up a 5 per cent. dividend in April last year. The reserve will then stand at nearly £12,000, so that our financial position is strong. With regard to the negotiations with our Continental allies, I am happy to say that, thanks to our Managing Director, who made sundry trips abroad to personally conduct them on behalf of the Company, they have resulted in the conclusion of new agreements for a term of many years. Whilst we are thereby fortified against competition of an international character, we preserve our absolute independence in our own territories. The same independence is enjoyed in their respective countries by the different national agencies with which we are connected by working arrangements. The shareholders will share with the Directors the regret they feel that Mr. Griffiths has felt compelled to resign the secretaryship. He has not only, as original shareholders know, filled the office from the formation of the Company, but was with Baron de Reuter when he started in 1851. After such a long period of service it is not unnatural that Mr. Griffiths under actual circumstances should wish relief from the mere routine duties of his post. But both the Board and Mr. Griffiths were alike disinclined to sever a connection which has been marked throughout with the most cordial relations; and accordingly it has been arranged that Mr. Griffiths, in relinquishing the secretaryship, shall still remain on the staff to give his advice and assistance whenever required. Possibly, after a period of rest he may be able, as he is willing, to resume a more active part in the administration.

The Hon. MARK F. NAPIER seconded the motion, which was carried unanimously.

The CHAIRMAN then moved the re-election to his seat at the Board of the Hon. Mark F. Napier.

Mr. HERBERT DE REUTER seconded the motion, which was agreed to *nem. con.*

Mr. NAPIER having briefly returned thanks,

Mr. T. L. COWARD proposed, and Mr. G. D. WILLIAMS seconded, the re-appointment of the auditors, Messrs. Welton, Jones and Company.

The motion having been agreed to,

Mr. COWARD proposed a vote of thanks to the Chairman and Directors for their successful conduct of the Company's business during the year.

Mr. LOVEDAY seconded the motion, which was carried unanimously.

The CHAIRMAN, in returning thanks, assured the shareholders that the Directors would continue to use their best endeavours to carry on the business of the Company in a satisfactory manner. He was sure that they would rejoice with him in thinking that Mr. Griffiths' services were not lost to the Company entirely; and when that gentleman's health was restored the Board would be again strengthened by his assistance.

The proceedings then terminated.

Great Northern Telegraph Company of Copenhagen.

The following shows the working account of this Company for the year 1889.—The account will be presented to the annual general meeting held at Copenhagen on the 26th inst.:—

	£ s. d.	£ s. d.
RECEIPTS.		
Balance on the 31st December, 1888		41,345 18 9
Traffic receipts	287,448 13 6

ELECTRICAL MACHINERY.

SOLE PROPRIETORS of the British, Indian and Colonial Patents,

THE PHOSPHOR BRONZE COMPANY (Limited),

87, Sumner Street, Southwark, London, S.E.

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

Including the sum of £685. 18s. 11d. brought forward from 1888, the amount available for disposal is £7,805. 0s. 10d., which the Directors recommend should be dealt with as follows:—To place £2,000 to the reserve fund; to transfer £500 in reduction of value of stores at branches; £340. 13s. in reduction of amount expended on exchanges on hand, which will then stand at £34,000; and to pay a dividend of 3 per cent., free of income-tax, on the paid-up capital of the Company, other than the vendors' shares, carrying forward £1,237. 2s. 8d. The returns from the Indian companies for the past year show an improvement. The Bengal and Bombay Companies have declared dividends of 4½ per cent. and 3 per cent. respectively on their issued capitals. The Telephone Company of Egypt has declared a dividend of 6 per cent. on its Preferred shares, free of income-tax, and carries forward £1,459. 1s. 4d. The dividends accruing on the shares held by this Company in the above-named companies have been brought into the accounts as usual.

The exchanges at Rangoon and Singapore continue to expand, but those at Madras, Maulmein, Colombo, and Port Louis, make but little progress. A change has recently been made in the management at Mauritius, involving some additional initial expense, which it is hoped may result in some improvement at that branch in the early future. The China and Japan Company has further developed its exchanges at Shanghai and Hongkong. The accounts for the past year show a surplus of £573. 16s. 4d., after paying debenture interest and writing off £300. 15s. 10d. in respect of depreciation and preliminary expenses. In order to provide that Company with more working capital, your Directors have taken up during the current year an additional £500 of its Seven per Cent. Debentures.

During the early part of last year a circular was issued by the Directors to each holder of the vendors' shares, asking them to meet the Board in reference to a re-arrangement of capital account. A meeting was held in response to this circular, but up to the present the negotiations have not resulted in an arrangement.

The Directors who retire at the present meeting are Mr. W. Addison and Mr. G. B. Frost, both of whom being eligible offer themselves for re-election. The auditors of the Company, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and offer themselves for re-election.

Telephone Company of Ireland (Limited).

Report and statement of accounts for the year ended December 31, 1889, to be presented to the eleventh ordinary general meeting of the shareholders, to be held at the offices of the Company, Dame-street, Dublin, on April 26, 1890:—The number of wires, exchange and private, under rental upon December 31, 1889, was 1,309. On December 31, 1888, the number was 970, being an increase of 339 for the year. This increase has ben caused principally by the opening of exchanges in Cork and Limerick, the number of subscribers to the exchange system in Cork having risen from 24 at the opening of the exchange on January 1, 1889, to 295 on December 31, 1889, whereas for the previous three or four years, during the whole of which time, the telephone service of that city was under the control of the Postal Telegraph Department, the number of exchange subscribers at no time exceeded 30. During the past twelve months, the wires of the Dublin system have been overhauled, a number of iron wires removed, and copper wires erected in their stead. The efficiency of the system has thus not only been fully maintained, but greatly improved by the removal of a prolific cause of faults and occasional breakages caused by the corrosion of the iron wires. The cost has been debited to maintenance. Notwithstanding these exceptional charges, and the general revenue having also to bear the interest upon capital expenditure in Cork, partly unproductive during the creation and growth of the system, the Directors are pleased to state that the net available revenue is sufficient to maintain the dividend of the previous year, a substantial sum being carried forward to the next account; but no addition is made to the reserve fund, because of the exceptional expenditure on the renewal of the wires by the substitution of copper for iron being more than equivalent to the sum usually set aside to the reserve fund. As additional capital is required for the extension of the business of the Company, and for the establishment of the proposed through trunk line connection between the telephone exchanges of Dublin and Belfast, the Directors offered to the shareholders 10,000 New Five per Cent. Preference Shares in proportion to their respective holdings. The subscriptions to these new shares have not been sufficient for the purposes required, and, as the Directors consider that the improved position and increasing revenue of the Company should enable them to raise the necessary funds at an interest not exceeding 5 per cent., they are unwilling to issue the shares as heretofore, as Six per Cent. shares. They therefore propose to submit the following resolution, to enable them to issue debentures to an amount not exceeding in the aggregate the unissued balance of the authorised issue of 75,000 Preference Shares:—

RESOLVED:—"*That the Directors be, and they are hereby, authorised to borrow any sum or sums of money, on such security and terms, as to interest or otherwise, as they may deem fit, and may secure the same by mortgage or by other debentures, or by bonds, or by any mortgage or charge of or upon the whole or any part of any property, funds, assets, or effects of the Company, including uncalled capital, but so that not more than £25,000 be owing at any time, and that no more than £10,000 be issued without the previous consent of a general meeting.*"

Owing to the amalgamation of the United Telephone Company, with the National and Lancashire and Cheshire Telephone Companies respectively, having been carried out by absorption of the United Company and the Lancashire and Cheshire Company by the National Company, it became necessary that this Company should enter into an agreement with the National Company adopting the agreement heretofore existing with the United Company. This agreement has already been signed, but before the same has effect it is requisite to make the alterations in the Articles of Association specified in the accompanying notice; and an extraordinary general meetng will therefore be held at the close of the business of the ordinary meeting for the consideration, and if approved, the passing of the resolution. In the event of this resolution being passed, a subsequent extraordinary meeting will be held for the purpose of confirming it. The amount standing to the credit of the net revenue account, including the balance of £325. 17s. 7d. brought from last account, amounts to £4,459. 4s. 10d., against £4,643. 17s. 8d. for the year 1888. Out of this sum there has been paid an interim dividend upon the Preference shares for the half-year ended June 30, 1889 (£1,071. 12s. 3d., paid in July last), also the interim dividend upon the ordinary shares (£875, paid in August) leaving an available balance of £2,512. 12s. 7d., as shown in the balance-sheet, since reduced by payment (on the 14th January) of the dividend upon the Preference shares for the second half of the year, to £1,392. 17s. 7d., which the Directors propose to allocate as follows:—For the payment of a dividend on the ordinary shares for the second half of the year, at the rate of 1¼ per cent. per annum (absorbing £1,093. 15s.), equivalent to £1. 2s. 6d. per cent. for the entire year, and carrying forward £299. 2s. 7d. to credit of the current year, as against £325. 17s. 7d. brought on from 1888.

In conformity with the Articles of Association, Mr. Valentine B. Dillon and Mr. Hermann G. Erichsen retire at this meeting, but are eligible for re-election.

The auditor, Mr. John M. Kean, also retires at this meeting, but is eligible for re-election.

CITY NOTES, &c.

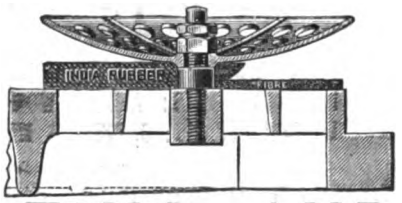
BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended April 18 amounted to £5,208.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended April 18th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,055.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended April 15th were £3,593, as compared with £3,742 for the corresponding period of last year.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 624.—Vol. XXIV. FRIDAY, MAY 2, 1890. Price Fourpence.

NOTES.

The novel lightning protector which was exhibited at the Institution of Electrical Engineers on Thursday last, and which we illustrate in the present issue, is the latest outcome of Dr. Lodge's remarkable researches on electrical oscillations. While it compares favourably with other lightning protectors in simplicity of design, there can be little doubt of the many theoretical advantages it possesses. The very striking experiment in which sparks were obtained between two adjacent portions of a thin wire shunting a short piece of thick copper, through which an oscillatory current was passing, conclusively establishes Prof. Lodge's main contention that discharges of the nature of lightning do not always choose the path of least resistance; and that consequently lightning-rods, although good conductors in the ordinary sense, may offer a dangerous impedance to a lightning discharge. Admission of this fact is quite consistent with the view, to which Dr. Lodge willingly subscribed, that practical experience shows that a very large measure of safety is secured by the use of lightning protectors constructed on present lines.

The protector itself consists of a number of spark gaps joined in parallel by means of coils of wire, whose object is to offer impedance to the discharge, and thus induce it to jump the gaps. The most rapidly oscillating currents will spark across the first gap, while the slower ones will choose the succeeding gaps, so that the discharge is rapidly sifted of its most dangerous ingredients, and the small portion which is conducted round is insignificant. The impedance offered by the coils, although negligible for telegraphic currents, is enormous for such rapid alternations as occur in lightning discharges. The protector will no doubt be able to compete with the excellent ones already in the market, and we may expect it to be used in future, not only, in conjunction with one of the others, for submarine cables, where the immense interest at stake renders it advisable to adopt every possible precaution against accident, but also for electrical instruments employed in telegraphy.

Incidentally, Dr. Lodge referred to a much-neglected matter deserving the attention of electricians, namely, the almost total absence of lightning protectors from electric lighting circuits. The letter of Mr. Sayers, published in our correspondence columns this week, is very opportune in this connection, since it relates some slight damage suffered by the insulation of leads in consequence of a lightning flash. The subject is an important one to consider now that mains are laid in such complex network under the streets.

In one of his experiments, Dr. Lodge used a protector consisting of two parallel discs of brass connected with the two terminals of the protected galvanometer. The capacity of the shunted condenser thus formed relieved the instrument of the dangerous effects of the electrical oscillations. The anomalous results obtained when the two plates of this plate protector were just touching were curiously similar to those obtained by Prof. Fitzgerald with his oscillation detector used in his recent lecture at the Royal Institution. Dr. Lodge suggests in explanation of these phenomena that an electromotive force is generated between the plates whenever a spark passes, and the shunted galvanometer is in consequence affected. Prof. Fitzgerald connected his galvanometer by long thin wires to the two knobs of the Hertz resonator, and observed an irregular deflection whenever there was sufficient resonance to cause a spark. It is to be hoped that the two phenomena will be further studied. They are very similar, and are possibly due to the same cause.

The suggestion that Faraday would have detected electrical actions within his electrified cage if he had used a galvanometer instead of electroscopes is another interesting example of the new light which recent experiments are throwing on old facts. The impedance offered by the cage to the passage of rapid oscillations would, according to Prof. Lodge, effectually stop all but comparatively slow vibrations; and these, although capable of affecting galvanometers in consequence of their magnitude, would be quite incompetent to affect electroscopes on account of their low tension.

The Paper on Electric Traction, read before the City Guilds Old Students' Association by Mr. Reckenzaun on Wednesday last, contained a most valuable collection of statistics, referring more especially to the amount of power required to electrically drive a car under different conditions of the line. A very interesting series of curves was exhibited, detailing the results actually obtained in Philadelphia on an experimental track about 1,000 yards in length, and containing several gradients and curves. No less than 230 journeys round the track were performed, and the connection between the driving current and the time is exhibited on the curves. An idea of the amount of labour involved

Digitized by Google

may be gathered from the fact that readings of the ammeter were taken every three or four seconds. Among the points more especially dealt with were the effect of snow and rain in modifying the tractive power required, and the economy brought about by skill in driving and the use of regulating apparatus. The author concluded by referring to several points attention to which would effect economy in electrical traction. An animated discussion followed, in which the varying conditions of electric traction on the Barking and Stratford lines and in collieries were referred to. The Paper and resultant discussion, which we hope to publish in our next issue, teemed with useful information, and form a valuable addition to electric traction data. The Old Students' Association is to be congratulated on securing such a highly practical Paper.

MR. DAFT, who was the first to assert the possible increase of adhesive power between the wheels and rails when an electric current was made to flow across the contact, has recently criticised Mr. CROSBY'S experiments to which we referred in our last issue. While agreeing with Mr. CROSBY that the effects are probably inappreciable with currents usually employed on electrical railways, Mr. DAFT still maintains his view that with the heavier currents he was formerly in the habit of working with, the effect is a very powerful one. The unsatisfactory nature which we have already alluded to of experiments made on a stationary car whose wheels are made to skid on the rails is pointed out by Mr. DAFT, who considers that in consequence Mr. CROSBY'S investigation is not at all conclusive. The subject is of sufficient interest and importance to render further experiments desirable, and it is to be hoped that Mr. DAFT will be able to follow the matter up.

THE Bill to amend the Electric Lighting Acts, which was brought in on Monday last by the LORD ADVOCATE, relates solely to Scotland. Across the border they suffer from an *embarras de richesses* in the matter of local authorities. A district, it seems, may be blessed at one and the same time by a Town Council, by Police Commissioners, and by Gas Commissioners. When the time arrived to apply for Provisional Orders the question naturally arose as to which of these three bodies should undertake the task, the general feeling being in favour of the Gas Commissioners doing the work wherever possible. To clear up this point is the object of the LORD ADVOCATE'S Bill. The schedule of Scotch local authorities annexed to the Act of 1882 is repealed, and another is substituted for it; and by Section 2 it is enacted that where the district of any Police Commissioners or Town Council is also within the jurisdiction of any Gas Commissioners, the latter may be appointed by the former as local authority for the purposes of the principal Act. We shall, therefore, soon have an opportunity of observing how electric lighting flourishes when managed by those intimately connected with the manufacture and distribution of gas.

IN his evidence before the Select Committee on Friday last it will be noticed that Sir BENJAMIN BAKER stated that they intended on the City and Southwark line to connect the motors direct to the axles. The absence of gearing is, of course, *per se*, a decided advantage; but it would be interesting to know the size and weight of the motors.

THE Paper read by Prof. RÜCKER at the meeting of the Physical Society on the 18th inst. was one of the most interesting and important communications presented to the Society for a long time past. The causes of the variations of magnetism on the earth's surface are still involved in mystery; and, indeed, the enormous magnitude of the secular variations forced CLERK-MAXWELL to the conclusion that we are not yet acquainted with one of the most powerful agents in Nature. A distinct advance in our knowledge has now been brought about by Profs. RÜCKER and THORPE, whose admirable work in connection with the Magnetic Survey is well known. They have apparently succeeded in tracing local variations in magnetic deviation to the influence of the magnetism of the geological strata in the neighbourhood.

A DESCRIPTION of Mr. BENEST'S gripping-grapnel for submarine cable work will be found in another column. Its principal utility would be when the ship was working near the broken end of a cable, which might slip over the prongs. Even in such cases, however, which do not occur so very frequently, the loose end generally twists around the cable on the other side of the grapnel, and so prevents slipping. Where a bight of cable is hooked it appears to be agreed amongst experts that it is an advantage to have the grapnel render under the cable, especially if there is any current; and if a cable were somewhat tender the extra strain caused by gripping and holding on to one part of it would certainly increase the chance of parting. Patents have been taken out for cutting and holding grapnels; but, so far as we know, Mr. BENEST'S is the first for holding only, and it would no doubt be an advantage for repairing steamers to carry one of these grapnels for use in special cases.

IN his plain-spoken address on "Fire Risks due to Defective Installations," recently delivered at Glasgow, Prof. JAMIESON emphasised two points which are still somewhat neglected by electrical contractors, namely, joints and cut-outs. Although it is, perhaps, too much to expect that the same care will ever be bestowed on electric light wire joints as is customary in the case of submarine cables, it is certainly desirable that this important work should receive greater attention than heretofore. Prof. JAMIESON, we are glad to see, is no advocate of that profuse use of cut-outs which is apparently considered by some to be the universal panacea. He even ventured to hope that the day would come when cut-outs would be entirely dispensed with. However, since cut-outs are used, it would be as well to extract the maximum of usefulness out of them. This desideratum, we need hardly observe, is not attained in an installation like that alluded to by Prof. JAMIESON, in which the same sized cut-out was used throughout.

THE Edinburgh Exhibition was opened yesterday with great success, and there was a large assemblage of spectators. The British exhibits are more forward than is usually the case, but

Digitized by Google

the foreign exhibits are somewhat backward. After the presentation of the address the DUKE OF EDINBURGH walked through the Machinery Hall, and expressed himself much gratified with all he saw.

Samarcand.—The local authorities at Samarcand propose to light the city by electricity.

Bromley.—A committee has been formed at Bromley, Kent, with a view to forming a syndicate for the electric lighting of Bromley, Bickley, and Chislehurst.

Society of Arts Conversazione.—This Society's *conversazione* is fixed to take place at the Natural History Museum, Cromwell-road, South Kensington, on Friday, June 27th.

Royal Society.—Amongst the Papers down for reading at the Royal Society yesterday was one by Dr. Hopkinson, F.R.S., on the "Magnetic Properties of Alloys of Nickel and Iron."

Indian Telegraph Department.—Colonel H. A. Mallock has been succeeded in his post of Director-General of Indian Telegraphs by Mr. W. R. Brooke, formerly Deputy Director-General.

Electric Lighting Acts Amendment Bill.—A Bill to amend the Electric Lighting Acts, 1882 and 1888, was brought in and read a first time in the House of Commons on Monday night.

Electric Traction in Mexico.—According to the *Courrier du Mexique*, the first electric railway in Mexico has just come into operation. The line connects Laredo with Nuevo-Laredo, and runs across the Rio Bravo.

Celluloid.—The Deutsche Celluloid Fabrik has recently introduced perforated celluloid plates for holding the active material of accumulator plates. It has been found to satisfactorily resist the action of sulphuric acid.

Alzano (Italy).—The first alternating current motor has been set up at Alzano Maggiore, where we recently announced the opening of a central station. The motor drives a centrifugal pump, and according to *l'Elettricita* works very satisfactorily.

Sunderland.—The Board of Trade have decided that, having regard to the objection lodged by the Corporation, they will not give their consent to the application of the Sunderland and District Electricity Supply Company for an electric lighting Provisional Order.

An Electrical Competition.—The Société Belge d'Électriciens announces that a prize of 500fr. will be awarded to the author of the best manual of electricity suitable for foremen and electrical artisans. The works, which must be in French, are to reach the secretary of the society not later than May 1, 1891.

Chelmsford.—On Wednesday last a deputation, consisting of the chairman and members of the Wimbledon Local Board, accompanied by Mr. Preece, paid a visit to Chelmsford in order to inspect the new light. Mr. Preece and the members of the deputation expressed themselves much pleased with what they saw.

The Brazilian Submarine Telegraph Company.—In our advertisement columns will be found the numbers of the 153 debentures of £100 each which were drawn on Friday last at the offices of this Company. These debentures will be paid off at par on July 31st next, at the Alliance Bank, Bartholomew-lane, E.C.

Railway Station Lighting.—From the *Elektrotechnischer Anzeiger* we hear that the railway stations at Bamberg, Regensburg, and Würzburg, will be lighted by electricity. At Bamberg 71 arcs and 736 incandescents will be required, at Regensburg 100 arcs and 818 incandescents, and at Würzburg 136 arcs and 847 incandescents.

The Wynne System of Urban Electric Traction.—We have received a small pamphlet setting forth the advantages claimed for Mr. Frank Wynne's system of electric traction (see *Electrician*, February 28, 1890, p. 427), and pointing out some of the defects, electrical, mechanical, and otherwise, inherent to the storage-battery, overhead and slot systems.

The Lighting of Gas Lamps by Electricity.—The Universal Gas Lighting Company of Jersey City (U.S.) have a mile of street lamps equipped with burners which are lighted and extinguished by electricity. The current used for this purpose is furnished by the electric light company, and the system has worked satisfactorily under very trying circumstances.

Barnsley.—At the last meeting of the Town Council the Park and Lighting Committee reported that part of Messrs. Robinson's woodyard had been fixed upon as the site for the proposed municipal central station, and that the terms quoted by the manager of the gas company for renewing the contract for lighting the public lamps had been sent back to the company.

Trial of the Manager of an Electric Light Company.—According to a telegram from New York, the evidence at the trial of Mr. Charles Pierce, local manager of the Brush Electric Light Company, on a charge of manslaughter, showed that the fall of an electric wire across Eighth-avenue, which resulted in a man's death, was purely accidental, and Mr. Pierce was acquitted.

Paddington Vestry.—The Board of Trade has refused to recognise the legality of the proceedings of the Vestry on Tuesday last week with regard to the selection of a Company to supply Paddington with the electric light.—Notices have been sent out for a special meeting of the Vestry to be held on Tuesday, May 29th, thus giving the month's notice required by the Board of Trade.

Lightning at Limassol.—On March 26th a sudden severe thunderstorm passed along the south coast of Cyprus, at Limassol. The port flagstaff (wood set in concrete) was struck and partially splintered. Within a few paces of the staff stand the Government offices, a high block of buildings, intersected with iron rain-water canals and pipes. A few paces further on is a very high minaret, with metal cap.

Manufacture of Shells by Electric Welding.—According to the *Electrical World* Lieutenant W. M. Wood, of the United States Navy, who is on leave of absence, and associated with the Thomson Welding Company, has devised a process for welding together the head and butt of shells by means of electricity, thus avoiding the long and costly process hitherto in vogue of boring out the solid metal.

Execution by Electricity.—The Philadelphia correspondent of *The Times* states that the United States Court at Syracuse, New York, has granted a writ of *habeas corpus* for Kemmler, whose execution this week by electricity was expected at Auburn prison. The writ was granted because the Constitution prohibits cruel and unusual punishments. It is returnable for June 17th, thus postponing the execution.

Artificial Gutta-Percha.—We are informed by Dr. Purcell Taylor that he has succeeded in making a new insulating material, having all the properties of gutta-percha. The new substance is very tough and elastic. A piece of iron covered with this "Purcellite" was, he states, hammered out flat, then bent and twisted until it broke, without even cracking the covering. The cost is said to be considerably less than that of gutta-percha.

Aberdeen.—The scheme which is being promoted by the Gas Committee of the Town Council for the utilisation of the water in the Loch of Skene for the production of the electric light has been remitted to Mr. Smith, the gasworks' superintendent, to report on. It is believed that a sufficient amount and fall of water could be obtained to produce the electricity required to supply the restricted area to be scheduled at the outset.

Institution of Electrical Engineers.—The students of the Institution met last Friday at the Sanctuary, when Mr. Ernesto Cirla read a Paper entitled "Lightning Conductors according to Modern Theories." Mr. Sydney Sharp took the chair. In the discussion which followed, the Chairman, Messrs. Barton, Wightman, Bone, Parson, and Müller took part. At the next meeting, to be held May 9th, Mr. Müller will read a Paper on "House Telephones."

Electric Tanning.—The use of electricity in tanning is not a modern idea, if a correspondent of a New York daily paper

Digitized by Google

is correct, who says the Persians have for ages believed in the efficacy of electricity in the preparation of leather. The Persians, it would seem, have been in the habit of exposing their leather on high places, especially on Mount Elwend, near Hamadan, and they affirm that lightning is a valuable agent in the curing of leather.

Lectures on Medical Electricity.—Dr. Tibbits will deliver a course of lectures on "Massage and Electricity," at the West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, at 5 p.m. upon the first Tuesday in every month, except August and September. Tickets of admission, for which no payment is required, will be issued to medical men upon application by letter to Dr. Tibbits, 68, Wimpole-street, W.

Chatham.—The committee appointed by the Chatham Board of Health to consider the application of the Chatham, Rochester and District Electric Lighting Company for the substitution of 42 for 21 years as the period at which the authorities could, under the Provisional Order, purchase the undertaking, have come to a conclusion which is in every way satisfactory, the Company's request being acceded to provided the Board of Trade will agree to the alteration.

Cardiff.—The Brush Company have issued a circular to their Cardiff customers, informing them that in consequence of the rules of the Board of Trade in regard to overhead wires, and of the decision of the Corporation of Cardiff not to consent to their application for a Provisional Order, they have no alternative but to close their lighting station. Next year they intend to renew their application for a Provisional Order, and trust then to obtain the consent of the Corporation.

Electricity in Engineering Workshops.—A Paper on this subject was read on Friday evening last at a students' meeting of the Institution of Civil Engineers, by Mr. C. Frewen Jenkin. The author gave a description of several workshop appliances driven by electro-motors, namely, a portable drill, driven by a one-horse power motor, an electrical tube-cutter for cutting tubes out of boilers, an electrical travelling crane, and a magnetic clutch, suitable for the gearing on the crane.

Hawick.—At a recent meeting of the Town Council, it was decided to reply to a communication from the Scottish House-to-House Electric Lighting Company to the effect that the Council would sanction the introduction of electric works in Hawick on condition that the Council should have the power to take over the works on payment of the outlay with the addition of 16½ per cent. at three years, 22 per cent. at seven years, and 30 per cent. at any time up to fifteen years, subject to depreciation.

Preston.—At the last meeting of the Town Council, on the motion of Alderman Satterthwaite, the Council passed a resolution assenting to the application by the Lancashire and Cheshire House-to-House Electric Lighting Company (Limited) to the Board of Trade for powers to light with electricity the borough of Preston. He explained that a short time ago they granted permission to a similar company, and the Streets and Buildings Committee had no objection to the Company named being placed on the same footing.

National Telephone Electrical Society.—On the 18th ult. Mr. Percy F. Currall read a Paper on "Batteries" before this Society, in which he discussed the merits of the various cells adapted for telephone purposes. Mr. W. Johnston read a Paper on the subject of "Galvanometers," on the 25th inst. The members discussed the question at great length, the principal instrument coming under notice being the D'Arsonval-Deprez, and the improvements recently suggested in this instrument by Messrs. Ayrton, Sumpner, and Mather.

A Chronological Chart.—We have received from Messrs. Sotheran and Co. a most elaborate chronological chart of the line of descent of the Royal Family of England, drawn up by Mr. Ilius A. Timmis, M.Inst.C.E. As the chart commences about 1,000 years back with King Egbert, it will be seen that it is of a comprehensive character. The work is adorned with Royal arms and crests, and under each Sovereign's name there is a brief *résumé* of the events of each reign. The compilation of this chart must have involved considerable labour and skill.

The Ferranti System in France.—The Ferranti system appears to be meeting with considerable success in France. The Compagnie Nationale d'Électricité has at the present moment Ferranti machines in operation at the Paris Municipal station, at Nancy, Rethel, Vierzon, Sens, Melun, and Hâvre, and concessions have just been obtained at Nimes, a town of 70,000 inhabitants, and at Troyes (Aube), a town of 65,000 inhabitants. Some successful public tests were also made a few days ago at Paris with an arc lamp designed by M. O. Pattin, which it is intended to run in connection with the Ferranti system.

Mica.—While the National Electric Light Association is still endeavouring to have the duty removed from copper, the owners of mica mines in North Carolina and New Hampshire are trying to induce Congress to place a 35 per cent. *ad valorem* duty on imported mica. The immense quantities of this material now used in the manufacture of electrical machinery and apparatus makes this a matter of considerable importance to American electrical manufacturers. Mica is now on the free list; and the proposed tax, says *Modern Light and Heat*, would cost one of the principal electrical manufacturing companies over $25,000 annually.

Prague.—The city of Prague claims to have been the scene of the first Industrial Exhibition ever held, namely, that inaugurated in 1791 in honour of the coronation of the Emperor Leopold as King of Bohemia. The centenary of this event is to be fittingly celebrated next year by a similar Exhibition, a great feature of which will be the section devoted to electrical inventions of Bohemian inventors, such as Pollak, Pulnj, Zenger, &c. The Exhibition will be lighted by 350 arcs and 650 incandescents. Luminous fountains, as at Paris, will be worked. Over 1,000 horse-power will be used for electrical purposes, the greater part for the transmission of energy.

Robbery of Accumulators.—About a month ago it was discovered that 38 accumulators, each weighing 33lb., had been stolen from the Théâtre des Variétés, at Paris. An inquiry was immediately instituted, but without result. A few days ago, however, says *l'Electricien*, a letter was received by the manager of the theatre announcing that the missing accumulators would shortly be forthcoming, and a few hours afterwards they arrived on a cart. The driver professed himself unable to give any information other than that he had been asked by some unknown individuals whom he had accidentally met in the street dragging the cells along in a truck, to take the accumulators to the Théâtre des Variétés.

Leicester.—The special committee appointed by the Council on November 26th last to consider the question of the present provision for telephonic communication in Leicester, and to report to the Council as to what means could be adopted for improving the same, report that they have been in communication with the National Telephone Company in reference to the facilities offered by that Company and the charges made by them. The committee find that the scale of charges for membership of a local exchange would be considerably below the present scale of the Post Office system, and are of opinion that it would be an advantage if the National Telephone Company would connect Leicester with their system, and recommend that the Council should give all reasonable facilities if the Company should decide to do so.

Junior Engineering Society.—On Saturday last a large party of "Junior Engineers" visited the Deptford station of the London Electric Supply Corporation. Great interest was displayed in the 1,500 horse-power Ferranti alternator, and in the Ferranti cable, large quantities of which were to be seen in the various stages of manufacture. A special feature of the Junior Engineering Society, which was formed in June, 1884, and now numbers close upon 100 members, are the visits paid by the Society to engineering and other works of interest. Visits were made last year amongst other places to the Central Institution, the City and Southwark Subway, and the Paddington Station installation. Candidates for admission to the Society must not be over 26 years of age, and must be engaged in the engineering or allied professions.

Municipal Electric Lighting Orders.—On Thursday last week a deputation from a large number of Town Councils and other local authorities attended at the offices of the Board of Trade with reference to the Model Order recently issued for municipal authorities. The objections of the local authorities to the Order had been formulated at a meeting in the Westminster Palace Hotel, and they were placed before the Board of Trade officials *seriatim*. The objections were of minor importance, and the amendments suggested by the deputation were accepted by the Board of Trade. A discussion arose as to the appointment of electrical inspectors. Under clause 29, a Court of Summary Jurisdiction may, on the application of any consumer, or of the undertakers, appoint inspectors. It was finally agreed that the Board of Trade should make these appointments. After all their objections had been discussed the deputation withdrew.

Electrical Engineering at King's College.—Great efforts are being made by the Council of King's College to meet the growing wants of the age in the direction of electrical engineering. The engineering department of this College has always had a high reputation; but now, thanks to the munificence of Lady Siemens, a new laboratory for electrical engineering, to perpetuate the name of her distinguished husband, and to be called the "William Siemens Laboratory," is to be constructed and fitted with every modern electrical appliance. Through the kindness of the well-known engineers, Messrs. Davey, Paxman and Co., of Colchester, the Council are enabled to equip a fine engine and boiler room with all the machinery requisite to provide the necessary power, and it is hoped that by this means the whole College will ultimately be lighted by electricity. A new chair of electrical engineering has been established, and the first Professor has been appointed, namely, Dr. John Hopkinson, F.R.S., the President of the Institution of Electrical Engineers, than whom no better selection could be made to undertake the direction of such a laboratory. It is hoped that the new arrangements will commence with the October Session.

The Lighting of the City.—On Tuesday last a special meeting of the Commissioners of Sewers was held to consider the applications for Provisional Orders by the London Electric Supply Corporation, the Metropolitan Electric Supply Company, the Brush Electrical Engineering Company, and the Laing, Wharton, and Down Construction Syndicate. Mr. Pannell moved that the Commission should not consent to the application of the London Electric Supply Corporation and the Metropolitan Electric Supply Company. These two companies had failed to come to terms, so they had no alternative but to oppose their applications. The motion was agreed to. A letter was then read from the London Electric Supply Corporation, complaining of unfair treatment in connection with the allotment of areas. Mr. Pannell said this Company was still unprepared to accede to the two salient points on which the Commission rigidly insisted, the sliding scale and the purchase clause. In two or three days, when the other contracts were absolutely decided on and sealed, this Company would have an opportunity of tendering on the same terms for the remaining area. At the same meeting, the Streets Committee reported relative to the recent inspection of the electric lighting system at Taunton, submitting also a report from Mr. Preece. The report was ordered to be printed and circulated.

The Agitation among the Telegraph Clerks.—In the House of Commons on Thursday last, in reply to several questions with regard to an official circular relating to meetings of officers of the Post Office, Mr. Raikes said what had been done relaxed the rule of the service on the subject of meetings outside the Post Office building for the discussion of official questions, and did not make the rule more stringent. The conditions on which Post Office servants were now allowed to meet were—(1) that ample notice be given to the local post office authority such a meeting and where it is proposed to hold it; (2) that the meeting will be confined to Post Office servants, and to those Post Office servants only who are directly interested in the matter or matters to be discussed; (3) that an official shorthand writer be present if required by the authorities. Mr. Raikes said that his wish was to be accurately informed as to the grievances of the telegraphists, and therefore he thought it desirable that a shorthand writer should be present at these meetings to furnish an authentic report of the proceedings. On the same day a deputation from the clerks of the Central Telegraph Office had an interview with Mr. Raikes at the General Post Office to present a memorial embodying their complaints against the present regulations of the service. Mr. Raikes, in reply, promised that the subjects dealt with by the deputation should receive the consideration of the Departmental Committee to which the grievances of the provincial clerks had been referred.

The Board of Trade and Electric Lighting Orders.—On Monday night, in the House of Commons, in reply to a question by Mr. Waddy, Sir M. Hicks Beach stated that the Board of Trade refused to proceed with the applications of the companies for electric lighting powers in Leeds in consequence of their not having obtained the consent of the local authority. The Corporation of Leeds, he said, state that a committee of their body are engaged in an exhaustive examination of the question of the supply of electricity, and they ask that the matter may be postponed until next year. The Board of Trade, in these circumstances, declined to dispense with the consent of the Corporation; but informed that body that, in the event of their not being prepared to apply for powers themselves next year, the department would have to consider whether they could refuse to grant powers to other promoters.—In the House of Commons on Tuesday night Sir M. H. Beach stated, in answer to Sir J. Pease, that the mere fact that certain members of local authorities were shareholders in gas companies within the districts of the local authorities would not of itself be deemed a sufficient reason to justify the Board of Trade in dispensing with the consent of such local authorities to Provisional Orders applied for by private promoters. If, however, it could be shown that the refusal of a local authority to give their consent was due to the votes of any members who were improperly influenced in giving these votes by their personal interest in local gas undertakings, he would be disposed to consider the expediency of directing an inquiry into an application to dispense with that consent.

The International Telegraph Congress.—Out of the 150 invitations to take part in the Congress at Paris, 90 have been accepted; 37 Government Administrations and 53 telegraph companies are included in the latter number. The festivities in honour of the Congress will be a banquet, an evening at the opera, and two official receptions and entertainments at Compiègne and Versailles. The British Post Office will be represented at the Congress by Mr. J. C. Lamb, Mr. H. C. Fischer, and Mr. P. Benton. These gentlemen will also represent the Cape Colony and Natal. The Australasian Colonies will be represented by their Agents-General as follows:—Victoria, Sir Graham Berry, K.C.M.G.; South Australia, Sir Arthur Blyth, K.C.M.G., C.B.; New Zealand, Sir Francis Dillon Bell, K.C.M.G., C.B.; Tasmania, Mr. E. N. C. Braddon.—The Telegraph Companies will be represented as follows:—African Direct, Sir John Pender, K.C.M.G., Most Hon. Marquis of Tweeddale, Mr. T. Fuller; Anglo-American, Mr. Henry Weaver, M. Jules Despecher; Black Sea, Sir John Pender, K.C.M.G., Sir James Anderson, Mr. Lewis Wells, M. Jules Despecher, Mr. W. Hibberdine; Brazilian Submarine, Mr. Thomas Fuller; Direct Spanish, Mr. Charles Gerhardi, Senor A. Aparicio; Direct United States, Sir John Pender, K.C.M.G., Mr. W. Ford; Eastern, Sir John Pender, K.C.M.G., Sir James Anderson, Sir Albert Cappel, K.C.I.E., Mr. Lewis Wells, M. Jules Despecher, Mr. W. Hibberdine; Eastern Extension, Australasia and China, Sir John Pender, K.C.M.G., Mr. Lewis Wells, M. Jules Despecher, Mr. F. E. Hesse, Mr. W. Hibberdine; Eastern and South African, Sir John Pender, K.C.M.G., Sir James Anderson, Mr. Lewis Wells, M. Jules Despecher, Mr. W. Hibberdine; Great Northern, Captain Suenson, Captain Hedemann, Mr. F. C. C. Nielsen; Indo-European, Mr. W. Andrews, Mr. F. Moll; Spanish National Submarine, Mr. Robert Gray, M. F. de P. Vazquez, Mr. W. F. O'Brien; West India and Panama, Mr. W. S. Andrews, Mr. H. Weaver; Western and Brazilian, Mr. W. S. Andrews, Major Wood, Mr. R. M. Cunningham; West African, Sir John Pender, K.C.M.G., Sir James Anderson, Mr. W. Payton, Mr. Lewis Wells, and Mr. W. Hibberdine.

MAGNETISM IN IRON AND OTHER METALS.*—XVI.

BY PROF. J. A. EWING, F.R.S.

(*Continued from page 616.*)

§ 69. **Cast Iron.**—Cast iron reaches a somewhat lower magnetisation than wrought iron or steel, even under strong forces. The intensity, when saturated, is about three-quarters that of wrought iron. In permeability, under moderate magnetising forces, and in coercive force, it generally resembles mild steel. Fig. 37 (from Hopkinson) exhibits half of a cyclic of magnetisation, for what is probably an exceptionally soft specimen of grey and cast iron, in which **the coercive force is barely double that of annealed wrought iron.**

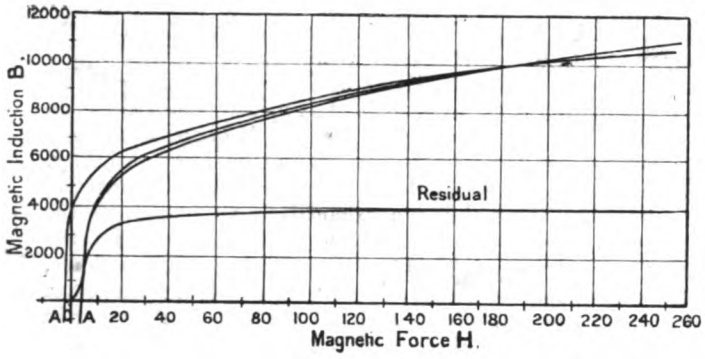

FIG. 37.—Cast iron.

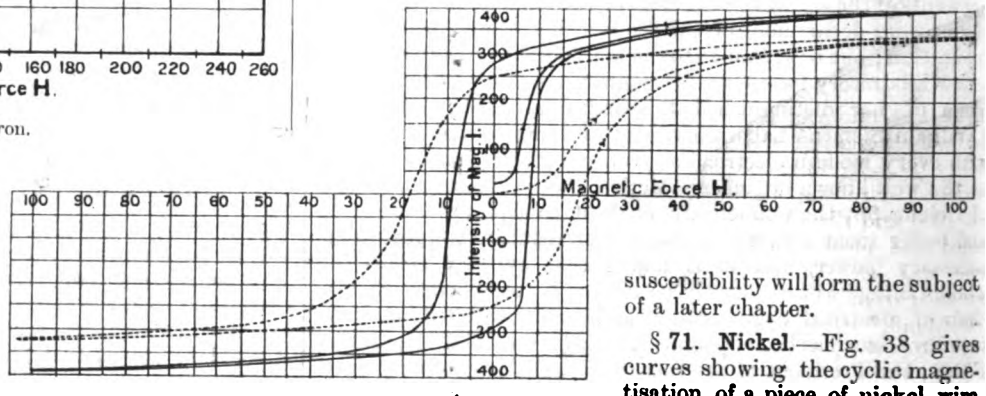

FIG. 38.—Nickel wire.

Annealed _____ Hardened by stretching .....

§ 70. **Non-Magnetic Steels.**—In certain alloys of iron there is a remarkable absence of magnetic quality. The presence of manganese in large quantities deprives the metal of nearly all its magnetic susceptibility. A notable instance occurs in the "manganese steel" of Mr. Hadfield, which contains about 12 per cent. of manganese and 1 per cent. of carbon. The permeability of this alloy is only about 1·3 or 1·5, and is sensibly constant in strong and weak magnetic fields. There is sensibly no residual magnetism, even after a very powerful magnetising force has been applied. A still more curious case is that of "nickel steel." Hopkinson* has found a specimen containing 25 per cent. of nickel to be practically non-magnetic under ordinary conditions of temperature, its permeability being constant and equal to about 1·4. Here we have two materials, nickel and iron, each strongly magnetic, becoming non-magnetic when combined. What makes this alloy peculiarly interesting is the further fact that when cooled to a very low temperature, it becomes strongly magnetic, and remains so after the temperature is again allowed to rise to ordinary atmospheric values. The effects of temperature on magnetic susceptibility will form the subject of a later chapter.

§ 71. **Nickel.**—Fig. 38 gives curves showing the cyclic magnetisation of a piece of nickel wire (0·068 cm. india meter, and 25·4 cms. long) first in the annealed state (full lines) and next after being hardened by stretching beyond the limit of elasticity (dotted lines).† The curves give I, not B. They show that under strong forces the magnetisation

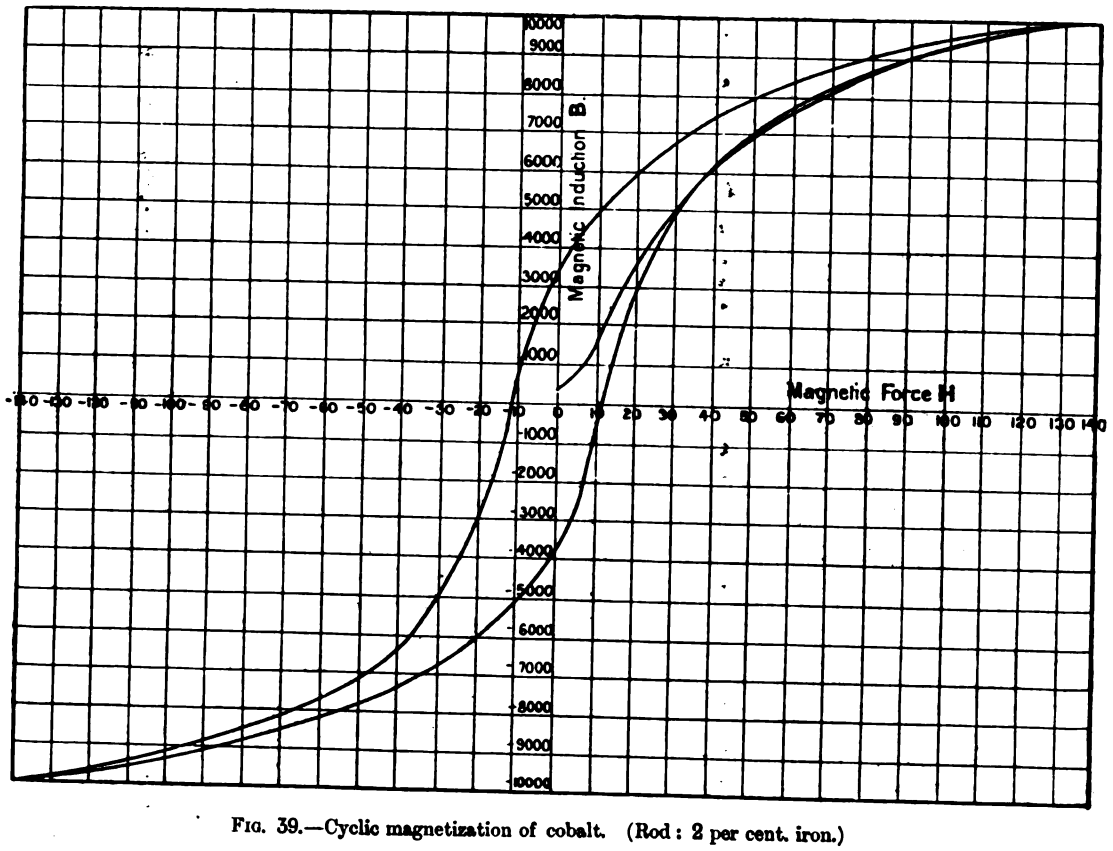

FIG. 39.—Cyclic magnetization of cobalt. (Rod: 2 per cent. iron.)

* *Proc.* Roy. Soc., Dec. 2, 1889. † *Phil. Trans.*, Vol. 179A, 1888, p. 327.

Digitized by Google

reached by nickel is greatly inferior to that reached by wrought or cast iron or ordinary steels. (The saturation value of I in nickel is $\frac{1}{3}$ or $\frac{1}{4}$ the saturation value in wrought iron.) The following numbers refer to the experiment of Fig. 38 when the wire was in the soft state :—

Annealed Nickel Wire.

H	I	κ
0	22	
4·0	36	
6·5	83	12·8
8·0	177	22·1
9·5	223	23·5
10·9	251	23·0
12·3	273	22·2
24·6	325	13·2
52·6	371	7·1
79·7	392	4·9
103·4	401	4·0
0	284	
-7·5	0	

The last numbers in columns 1 and 2 of the table show the residual magnetism and coercive force. The greatest susceptibility ($\kappa = 23·5$) corresponds to $\mu = 283$. In the test with hardened wire the maximum susceptibility κ was only 8·3 ($\mu = 105$) and the coercive force was 18. The curves for annealed and mechanically hardened nickel differ in much the same way as the corresponding curves for annealed and hardened iron.

Rowland,* using a ring of cast nickel, found a maximum susceptibility of 17 6 (permeability 222), and reached a value I equal to 434 with a force H of 104.

§ 72. **Cobalt.**—Cobalt has decidedly more capacity for magnetisation than nickel. Under the action of a strong field it takes up about as much magnetism as cast iron ; it has, however, comparatively little susceptibility when the magnetising force is weak.

Fig. 39 exhibits an experiment on the cyclic magnetisation of a cobalt rod (containing about 2 per cent. of iron), cast and turned, and tested, within a yoke, in the manner described in § 58, the magnetism at each stage being determined by summing the ballistic effect of successive steps. There was a small amount of initial magnetism, not removed when the experiment began. The greatest permeability occurs when the force is about 25, and its value is 174, which corresponds to a susceptibility of 13·8. Rowland, using a cast cobalt ring, found a maximum susceptibility of 11·2.

The curves for cobalt have a rounded outline recalling those for hardened iron. One effect of this is that the residual magnetism is comparatively small. The coercive force in Fig. 39 is 12.

(To be continued.)

THE CLARK STANDARD CELL.

BY PROF. H. S. CARHART.

My attention has only quite recently been called to Lord Rayleigh's remarks on the above subject in *The Electrician*, January 24, 1890, p. 285, referring to my Paper in the *Philosophical Magazine* for November, 1889.

Lord Rayleigh, who has made such important contributions to our knowledge of the conditions requisite for a good standard cell, says that "the lower temperature coefficient would be an advantage in itself, if it could be obtained without loss in other respects." This advantage I think I have secured, not only without loss in other respects, but with certain additional advantages. The low coefficient of ·00039 is not due to the separation of the zinc from the mercurous salt, but is obtained by standardising the zinc sulphate solution. My solution is saturated throughout, not at the temperature recommended by Lord Rayleigh, but at zero C. I adopted this method because an increase in the density of the zinc sulphates operates to lower the E.M.F. If, therefore, the sulphate solution is saturated at say 30° C., when the temperature falls the excess crystallises out, and the E.M.F. rises for two reasons, one due directly to the change in temperature, the other to a diminution in the density of solution. When the temperature rises the zinc sulphate again goes into solution, with the result of affecting the E.M.F., and of making the solution of unequal density at different levels. This inequality continues till rectified by diffusion ; and if the change in temperature is not very slow, it may perish for a long period. Hence the temperature coefficient of such a cell, determined by means of somewhat rapid variation of temperature, will be lower than when it is derived from a series of observations extending over a long period. This is clearly brought out in Prof. Threlfall's Paper in the *Philosophical Magazine* for November, 1889. For rapid temperature change he obtained a coefficient of ·00040 in the case of a cell made up in accordance with Lord Rayleigh's directions.

On account of this inequality of density where undissolved crystals of zinc sulphate are present, the zinc is sometimes eaten away at the surface of the liquid, where the density is least, and is deposited again on the zinc rod at the surface of the mercurous salt, where the liquid in contact with zinc sulphate crystals is saturated. This is probably due to the difference of the E.M.F. between the zinc and the solution at different densities. These disadvantages are avoided by saturating the solution at a temperature lower than that at which the cell is to be used. The change in E.M.F. with temperature is then reduced to a purely thermal one. In order to use this method the greatest care must be employed in making the mercurous sulphate, so that it can be washed entirely free of acid without turning yellow. The paste must be poured into the tube as soon as it is mixed, to prevent evaporation. I do not use any zinc carbonate, and my cells now show too high an E.M.F. when first set up, in consequence of any acid in the salt. It was an inadvertence on my part not to notice that Lord Rayleigh's sample of mercurous sulphate turned yellow only on rubbing up with *zinc carbonate*, together, of course, with zinc sulphate. Since reading Lord Rayleigh's article in *The Electrician* I have tested some of my mercurous sulphate with zinc sulphate and zinc carbonate together, and find that it remains quite free from any yellow colour ; so that I apparently have mercurous sulphate at least approximately free from admixture with the mercuric form.

The method which I have adopted requires efficient dealing to prevent evaporation. Cells subjected to considerable changes of temperature sometimes show a separation of the sealing compound from the glass, thus allowing the liquid of the cell to come out by capillary action. This appears to be due to a large difference in the coefficients of expansion of glass and the sealing material. I have recently adopted a new device to diminish this difference, but it is too soon to speak positively about it.

If the zinc dips into the mercurial salt zinc displaces mercury, thus increasing the density of the solution. It is on this account that I separate the zinc entirely from the solid mercurous sulphate. I have recently observed that M. Guoy does the same thing with his mercury oxide cells. Since a standard cell is not supposed to do any work, the density should remain constant when the conditions are such as to prevent local action.

The Protection of Iron from Rust.—Herr Haswell, of Vienna, proposes to protect iron from rust by coating it with a layer of electrolytically deposited manganese dioxide. The iron is made the anode of an electrolytic bath, containing a ·05 to ·5 per cent. solution of chloride or sulphate of manganese, and from 5 to 20 per cent. of ammonium nitrate. Carbon is used for the cathode. On passing the current the iron becomes coated with a firmly adherent and inoxidisable film of manganese dioxide.

* *Phil. Mag.*, November 13, 1874.

THE LODGE LIGHTNING GUARD.

As we are unable to publish Dr. Lodge's Paper in the present issue, owing to the fact that it was delivered only from notes, a brief description of the instrument itself may prove of interest to those of our readers who were not present at the meeting last week.

The chief feature of Dr. Lodge's ingenious and beautifully-simple device for protecting cables and electrical apparatus from injury by lightning and high-tension discharges in general consists in placing a *number* of air gaps, or their equivalent, between the line and the apparatus to be protected. This principle, of course, admits of a variety of practical solutions, and in Fig. 1 we have a diagramatic representation of one of the methods proposed by Dr. Lodge. L and E are terminals, connected respectively with the line and with earth, T_1T_2 are

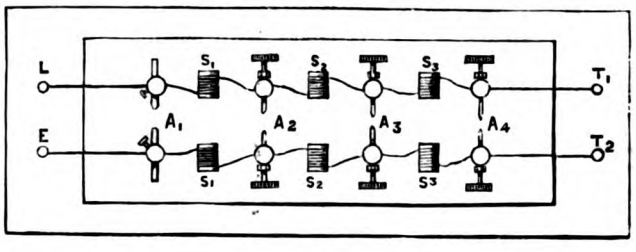

Fig. 1.

terminals in connection with the instrument to be protected. A_1, A_2, A_3, A_4 are air gaps, and S_1S_1, S_2S_2, S_3S_3 are impedance coils. The air gaps, it will be observed, decrease in width, and the wire composing the coils becomes gradually finer. The broad effect of this particular arrangement, which we hasten to add is not greatly insisted on by its author, is to

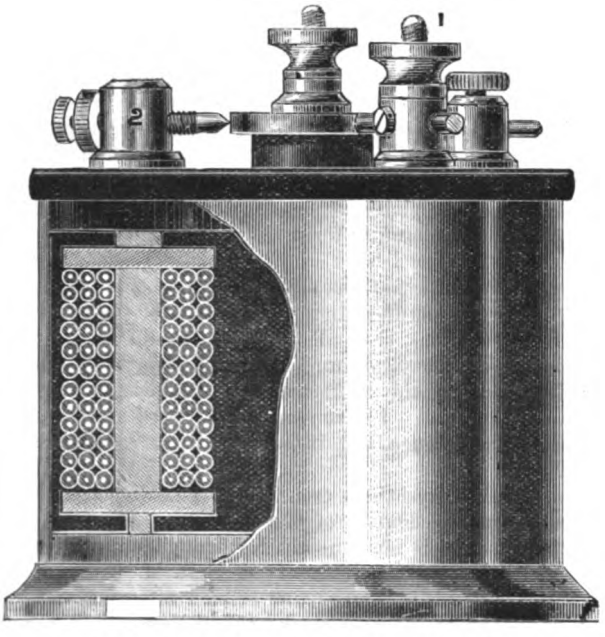

Fig 2.—The Lodge Lightning Guard (circular pattern).

present an increasingly difficult path to the discharge in the direction of the instrument which it is required to protect, and an increasingly easy path to earth. The coils may be composed of the same wire throughout, the air gaps may be of the same width and the terminals may be connected up in a variety of ways. A lightning-conductor of this form, it is obvious, offers great self-induction on the one hand, and dielectric weakness on the other, to the lightning, and air-resistance obstruction on the one hand, and thick wire conduction on the other, to the useful current. The superiority of this device over ordinary single air-gap protectors, at any rate in the case of powerful discharges from a large Wimshurst machine, is most marked. It is unnecessary to add that the self-induction of the coils is inappreciable for ordinary currents, and that they contain no iron cores. In Fig. 2 we have a perspective view and in Fig. 3 a diagram of the connections of an actual protector of the circular pattern, as constructed by Dr. Alexander Muirhead. The central boss is connected to the brass case by means of a rod down the centre. Underneath, in the base of the instrument, is a screw to which a direct connection with the earth is made. The screw on the central boss at the top

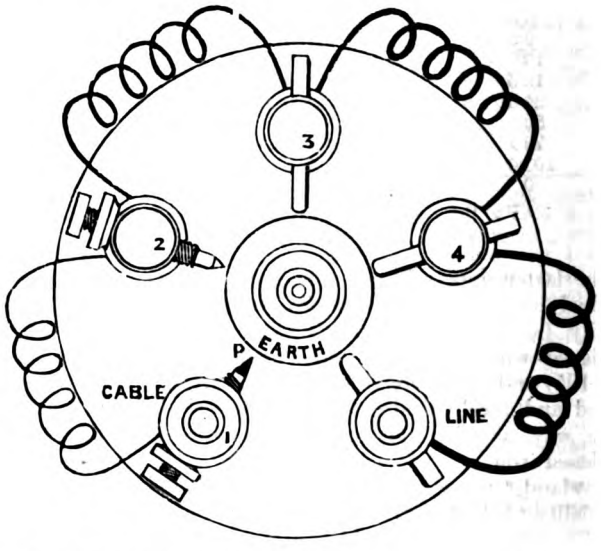

Fig. 3.—The Lodge Lightning Guard (circular pattern). Diagram of connections.

is only used when a handy earth is wanted for an instrument. The first projecting rod is of platinum, the second of brass, and the remaining three are of copper. This arrangement, it will be seen, is equivalent to that shown in Fig. 1, with the lower row of coils omitted.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 18th April, Prof. A. W. Rücker, F.R.S., communicated some of the results most recently obtained in the Magnetic Survey upon which he has been engaged in conjunction with Prof. Thorpe for some time past.

The Professor observed that in the account of their work already published they had pointed out that the tracts of country surveyed could be divided up into distinct districts; and the distribution of the magnetic force in these districts had led them to form the provisional hypothesis that the variations were mainly due to the presence of large masses of magnetic rocks. If the hypothesis were correct it was to be expected that the vertical magnetic force would be a maximum over the central portions of such a mass, and that the horizontal forces would be deflected towards the centre. This had only been absolutely proved to be the case in two instances, though in other instances it appeared highly probable.

In order to investigate the matter further they selected two test districts for more minute examination last summer. The districts selected were the west coast of Scotland, and Lincolnshire and Yorkshire. These were selected because, in the first place, the local variations in these districts were very considerable, owing, probably, to the large masses of basalt present in them, and in the second place because they lay near the boundaries of the survey, so that any errors in the calculation of the normal force would be most likely to show themselves there. Magnetic maps of these districts, plotted from the observations made last summer, were then exhibited.

The map of the Lincolnshire and Yorkshire district exhibited a magnetic ridge line, coinciding with the line of the Wolds, and along this ridge line the local variation in the vertical force was a maximum, while the horizontal forces were deflected towards it at points on either side of it. The map of the West Coast of Scotland showed

Digitized by Google

that the distribution of the magnetic force was of the character which would be expected to follow from the presence of a large submerged mass of magnetic rocks off the south-west coast, due south of the Hebrides. The authors had calculated what the forces ought to be according to some observations made by Welsh in 1859 and 1860, and they found that they led to the same conclusions as their own.

In conclusion, Prof. Rücker stated that an application was being made to the Royal Society to assist in carrying out further observations.

DISCUSSION.

Mr. WHIPPLE complimented Professors Rücker and Thorpe on the great advances made by them in the carrying out of Magnetic Surveys. General Sabine, in his Magnetic Surveys, had only paid attention to the direction of the magnetic force, without considering its amount; and the early death of Welsh, who had first called attention to the large deviations in the Hebrides and other parts of Scotland, put a stop to the work on which he was engaged in 1859 and 1860. He did not think it likely that Welsh had any idea of the interesting relation between the magnetic deviation and the local geological formation pointed out by Professors Rücker and Thorpe. Sabine's attention had been almost exclusively devoted to the horizontal force, and the same was the case with the Admiralty observations until quite recently. The map of the lines of magnetic force constructed by the late Sir F. Evans was founded only upon the rough observations made by sailors to determine the variation of the compass. The older surveys were all made by simply counting, by the aid of an ordinary watch, the oscillations of a short magnet, which was merely compared before and after the voyage with a standard permanent magnet kept at Woolwich; and this standard magnet was assumed to remain constant, its intensity of magnetisation being assumed as unity. No temperature corrections were made in these surveys. The small effects observed by Professors Rücker and Thorpe were, therefore, completely masked.

Professor CAREY-FOSTER expressed his admiration of the manner in which the survey had been carried out, and considered that the observations were likely to lead to results of great interest and importance.

The SECRETARY then read a translation of a Paper, which had been communicated in French by M. Osmond, on

"A Theory of Permanent Magnetism."

The author pointed out that iron exists in at least two molecular states—soft iron, annealed and slowly cooled, which he has called α-iron; and this, when raised to a certain critical temperature, passes into the second form, which he has called β-iron, and the latter state is partly retained on cooling, especially if the cooling is rapid and the iron contains a considerable proportion of carbon and manganese. Electrolytically-deposited iron is of the β variety, which may also be produced by cold hammering. The author then regards a bar of steel, after allowing for the carbides, phosphides, and sulphides which may be mixed with it, as consisting of an intimate mixture of the two varieties in proportions which are determinate at any one point, but may vary from point to point. He supposes the β-iron to form a sort of porous non-magnetisable framework, interlaced with polarisable and mobile particles of α-iron. These particles after displacement, caused by placing the mass in a magnetic field, will be prevented from returning completely to their original positions by the presence of the rigid framework of β-iron, and so a permanent magnet will be formed.

The Paper was accompanied by a diagram in which the author attempted to depict his theory graphically. He thought it explained the fact that expansion, shocks, or vibration tend to diminish the permanent magnetism of a bar, as any of those would tend to make the framework more open, and, therefore, allow the polarisable particles to move more freely. The magnetising force required to produce saturation would increase with the proportion of β-iron, which was in agreement with the experimental fact that iron containing a large proportion of carbon or of manganese—Speigel iron, for example, which contains 25 per cent. of manganese—is non-magnetic. The theory also explains the difficulty, after a bar has been magnetised to saturation, of magnetising it to the same extent in the opposite direction; this being due, on the author's theory, to some of the particles of the α-iron being immovably entangled within the framework of β-iron.

DISCUSSION.

Prof. AYRTON observed that the author's theory would not afford any explanation of the enormous effect of the presence of a small proportion of tungsten in the iron.

Mr. SWINBURNE stated that some experiments which had recently been made showed that the permeability in a given direction is different after magnetisation in a direction at right angles to this, from its value previous to such magnetisation; and the author's theory, or theories of a similar character, would not suggest any explanation.

BOOKS, &c., RECEIVED.

"Gas and Petroleum Engines." A Practical Treatise on the Internal Combustion Engine. By William Robinson, M.E. (London: E. and F. N. Spon.)

"Chronological, Historical, and Heraldic Charts of the Royal House of England, from King Egbert to the Present Time." By I. A. Timmis, M.Inst.C.E. (London: Henry Sotheran and Co.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, May 2nd.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Théophile Gautier." By WALTER H. POLLOCK, M.A.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: "The Distribution of Flow in a Strained Elastic Fluid." By C. A. CARUS-WILSON. "Photographs of Rapidly Moving Objects," and "The Oscillating Electric Spark." By Prof. C. V. BOYS.

SATURDAY, May 3rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Colour and its Chemical Action." By Captain W. DE W. ABNEY, R.E., F.R.S.

MONDAY, May 5th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7.30 p.m. Ordinary Meeting. Paper to be read: "Breakwater Constructions." By F. H. CHEESEWRIGHT, M.Inst.C.E.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture: "Sugar, Tea, Coffee, and Cocoa, their Origin, Preparation, and Uses." By RICHARD BANNISTER.

TUESDAY, May 6th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Art of Engraving." By LOUIS FAGAN.

INSTITUTE OF MARINE ENGINEERS.

7:30 p.m. Paper to be read on "Electricity." By J. MCFARLANE GRAY.

ROYAL VICTORIA HALL.

7:30 p.m. Science Lecture: "Birth and Death of Mountains." By W. W. WATTS.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "The Screw-Propeller." By M. SYD. W. BARNABY, M.Inst.C.E.

WEDNESDAY, May 7th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Aim and Scope of Higher Technical Teaching." By Dr. PERCY F. FRANKLAND.

THURSDAY, May 8th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Flame and Explosives." By Prof. DEWAR, F.R.S.

SOCIETY OF ARTS.

5 p.m. Indian Section: "The Western Frontier of China." By DEMETRIUS BOULGER.

8 p.m. Lecture: "Design Applied to Wood Carving." By LEWIS F. DAY.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Discussion on the following Paper: "On a Lightning Guard for Telegraph Purposes, and on the Protection of Cables from Lightning." By Dr. OLIVER LODGE, F.R.S. Paper to be read: "The Treatment, Regulation, and Control of Electric Light by the Legislature and the Board of Trade." By Major P. CARDEW, R.E.

CHEMICAL SOCIETY.

8 p.m. Extra Meeting. Exhibition of Apparatus, &c.

FRIDAY, May 9th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Colour Vision and Colour Blindness." By R. BRUDENELL CARTER, F.R.C.S.

SATURDAY, May 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Recent Excavations in Greece." By CHARLES WALDSTEIN, Ph.D.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.			6 months.			12 months	
For Foreign Parts and Colonies:—	s.	d.		s.	d.		s.	d.
Within Postal Union	6	6	...	12	6	...	24	0
Aden, Borneo, Ceylon, China, India, Japan, Java Labuan Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7	6	...	14	6	...	28	0
The rates for the United Kingdom remain as follows:—	5	0	...	10	0	...	19	6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo, 5s., postage extra.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which is still further enlarged and improved (making 850 pages), is NOW READY. Orders should be forwarded at once to the Publishing Offices, Salisbury-court, Fleet-street, London, E.C.

THE EDINBURGH EXHIBITION.

The International Exhibition which was formally opened at Edinburgh yesterday is the happy outcome of what was at first a not very promising project. Judging by present appearances, its career during the ensuing season will be as prosperous as such undertakings usually are, and possibly even more so. For the Edinburgh Exhibition starts with many local advantages which some of its predecessors have not enjoyed, and with a management the enterprise and activity of which leave nothing to be desired. This is the more gratifying because of the inauspicious circumstances under which the idea was started. At first it was intended as an Electrical Exhibition only, or at all events chiefly; and certainly no part of the United Kingdom could show a better reason than Scotland for such a mode of advancing an industry in which that country, with its abundance of water-power and other natural resources, is so well fitted to take the lead. It was argued also that so rapid was the progress of electrical inventions that,

Digitized by Google

although following close on the heels of the Paris Exhibition, there was ample room for another in the northern British capital. These arguments, however, did not suffice to win adherents from over the border; and at one time it seemed likely that English electrical firms would decline to take part in the venture. It soon became evident to the promoters, therefore, that the local conception would have to be abandoned, and an International one taken up in its stead. With this alteration of programme there followed necessarily a great modification in respect to the electrical character of the Exhibition; and although electrical exhibits have preference over others in respect to space and position, as a whole the attraction for the general public will not differ materially from those of International Exhibitions generally where the special objects are less pronounced.

This change of plan is by no means to be regretted. A special Electrical Exhibition, it is true, is not much needed just now; but since electricity in some shape or another is bound in these days to form an important feature of any large Exhibition, it would not benefit the electrical industry to be associated with an enterprise which, for want of ordinary business foresight, might be a financial failure. In plain words, it is better to be part of a successful show than to be the whole of an unsuccessful one. And as a matter of fact the industrial applications of electricity, although daily increasing in number and importance, are beginning to lose some of the interest which they aroused in the public mind in the early pioneering days of the science. We are glad, therefore, to notice that the Edinburgh International Exhibition possesses apparently other elements of popularity. It has the advantage of a picturesque situation near to one of the most interesting historic cities of the world. Railways and tramlines run close by its doors; and the grounds which surround it are not only beautifully laid out, but amply provided with outdoor recreations for the people. Inside there is a spacious concert hall and various other places of entertainment; while the collections of sculpture and art treasures will satisfy the tastes of the more refined pleasure seeker. The building itself, although of considerable dimensions, having proved too small for the space demanded, additional annexes have been provided far in excess of what was contemplated; and the exhibits are of that miscellaneous description which commands the attention of ordinary sightseers. When it is added that the exhibition is opened under Royal patronage and will probably be visited by the Queen in person, its prospects seem to be exceptionally good.

We have mentioned that the space allotted in the first instance had to be greatly enlarged, chiefly to meet the demands from Italy, France, Belgium, Germany, and the British Colonies; but, even then the right of rejection or curtailment has had to be exercised very freely. As regards electrical exhibits, however, the promoters have adhered to their original design so far as to accept all applications that have been received; and the result has been very satisfactory. We hope to give some account of the more important electrical exhibits in due course; and, for the present, we confine ourselves to the remark that the hall set apart for electrical and other machinery is 680 feet long and 150 feet broad, and is already fairly well filled up. The building is lighted by electricity, as a matter of course, and sufficient steam-power is provided on the spot to run the dynamos for purposes of exhibition or testing. Outside there is an electrical railroad, and a telpher line; and on the neighbouring canal there are to be four electric launches, by means of which passengers will be conveyed—or shall we say moteled?—to and from the Exhibition grounds. Thanks to the exertions of the Electrical Trades' Section of the London Chamber of Commerce, advantageous terms were made with the promoters at Edinburgh, both as regards the insurance and the charges for space. As to the latter, it was agreed that the electrical trades should deposit the fees common to all exhibitors, but that in proportion to the profits of the Exhibition those fees shall be remitted when the affairs are wound up. The electrical industry will thus have a direct interest in the prosperity of the Exhibition; and it is to be hoped that this experiment in profit-sharing, so to speak, will establish an encouraging precedent for future use. One other point on which the Electrical Trades Section was particularly anxious to obtain some clear understanding has not yet been satisfactorily settled. We refer to the question of tests and awards. Alternating-current machinery and transformers were particularly referred to as standing in great need of some reliable tests at the present moment; the difficulty was to agree upon the jury who should do the testing. It may be hoped that this obstacle will be overcome before the Exhibition closes, and that such a capital opportunity will not be allowed to slip owing to the jealousies of exhibitors or the backwardness of competent and impartial examiners.

AYRTON AND PERRY'S TWISTED STRIP VOLTMETER.*

At the Physical Society some years ago, I announced that a strip of material to which a permanent twist had been given behaved in much the same way as one of our now well-known springs; that is, when it was elongated by axial forces there was a relative rotation of the ends; in fact, the twist gets less. As some people have a difficulty in understanding what I mean by a twisted strip, I have prepared Fig. 1 to illustrate my meaning.

Fig. 1.

The relative rotation is perhaps better seen in a strip whose permanent twist is right-handed at one end and left-handed at the other. If a point be attached to the middle, as shown at A Q B, Fig. 2 or Fig. 3, and the ends are pulled out, the pointer rotates. This double-twisted strip we have applied to weighing machines, aneroid barometers, and many other instruments, such as wire-testing machines; and I can recommend its use in all cases where a force has to be measured, and where it is not advisable that there should be a considerable amount of yielding. For example, spring balances are sometimes used acting directly on specimens as testing machines; but when the specimen breaks, the recoil of the balance is likely to cause it to get out of order. Again, if a double twisted strip is used as a tension piece in a jointed structure, a pointer set at its middle will indicate the pull at any time.

The only likely suppositions I could make in thinking of what occurs in a twisted strip were, first, that two spiral filaments symmetrically disposed relatively to the axis resembled the two threads in a bifilar suspension, if a sufficiently short length of strip was considered; second, that the tensile stress was uniform over a cross section of the strip at right angles to the axis; third, that the resisting couple was due to the torsional rigidity of the section of the strip still taken as rectangular.

These suppositions lead to the result that

$$\phi \propto \frac{w l n b}{t^3},$$

* A Paper read by Prof. Perry at the British Association Meeting at Newcastle, 1889.

Digitized by Google

when w is the axial force, l the length of the strip, n the number of complete spires given by permanent set to unit length of the strip, b the breadth of the strip, and t its thickness, ϕ being the small rotation produced by the small load, w.

Now, such experiments as I have made hitherto on steel strips point rather to some such law as the following, being roughly correct,

$$\phi \propto \frac{w\,l}{b\,t^3};$$

that is, the rotation seems to be independent of the amount of twist originally in the strip, and instead of increasing as the breadth of the strip increases, it diminishes. It is evident that the action is a much more complicated one than I had imagined.

Now, I found that when a double-twisted strip was placed in tension and its ends were fixed, the pointer rotated if the temperature was altered, so that its use as a pyrometer or thermometer was possible.

In this instrument before you (Fig. 2) we have a tube A H D C B, about two-thirds of whose length, A H D, is brass and about one third, C B, is iron. A double-twisted strip of platinum-silver is in tension in the axis of the tube with its ends fastened to the ends of the tube, but one of them electrically insulated from the tube. The tube just at the middle of its length, D G, becomes a strong thin bracket, which enables a pointer, Q P, attached to the strip to make a rotation of nearly 360 degrees,

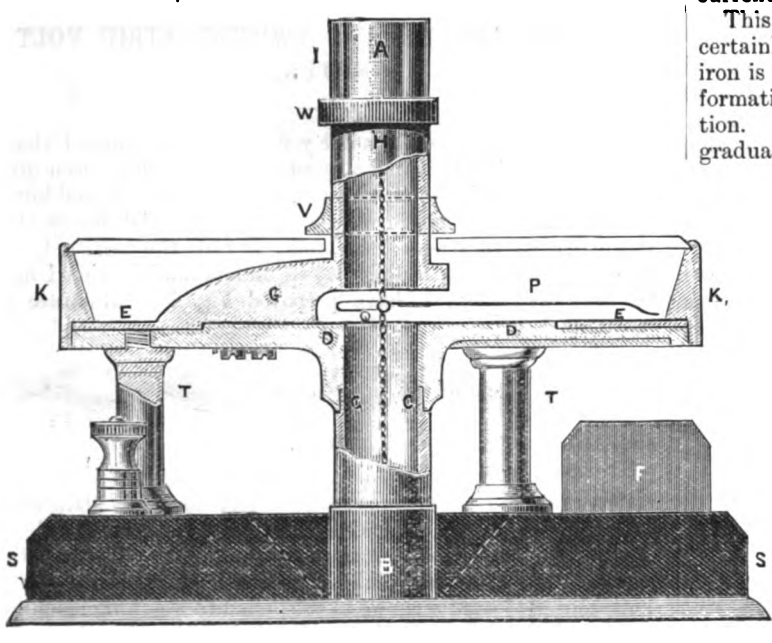

Fig. 2.

making the current once in every minute. This process is performed by the seconds hand of a clock passing into and out of a bath of mercury in every revolution. It is quite wonderful to observe the complete change in elasticity produced in a strip by this kind of fatigue. The strip seems to undergo no alteration afterwards by mere use or disuse; but it is my intention to test this by many months' experience before allowing these instruments to be manufactured. The two instruments before you are the only two yet made.

I had hoped to be able to show you one in which the strip is of flashed carbon. Here are specimens of twisted carbon strips, but unfortunately they are all too coarse for a 50-volt instrument, which is what I intended them for.

For accumulator work the 2½-volt instrument is greatly needed, and I prefer this form to our hot-wire instrument, because of its great simplicity and its needing so very little adjustment in manufacture.

For alternating currents this 2½-volt instrument may be used through any range whatever by placing a small transformer on the base of the instrument. The little transformer before you transforms in the proportion of 50 volts to 1, so that the instrument may be used on the ordinary 100 or 110 volt circuits. By using a different winding on the transformer the same instrument may be graduated for a 1,000-volt circuit. I find that this transformer maintains the same proportionate transformation of voltage whether the frequency of alternation of current is 50 or 100 per second.

This pleasing result was not altogether unexpected, but it certainly was unexpected to find that if a sufficient quantity of iron is used in the transformer there is a constant ratio of transformation of *current* for quite different frequencies of alternation. Hence, I find that this 2½-volt instrument may be graduated as an ammeter up to 1,000 amperes or more, or a

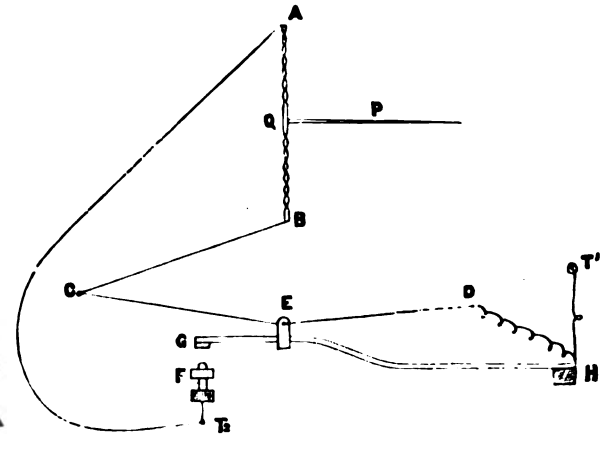

Fig. 3

and the arrangement of the bezel and dial will readily be understood without any further description. A and B are caps to the ends of the tube. When the cap A is turned, the initial pull in the strip is altered, and thus furnishes a zero adjustment.

When the various parts of this instrument are all at the same temperature the pointer remains in the same position whatever that temperature may be. When a current is passed through the strip, the pointer records the difference of temperature between the strip and its case, and hence the readings of the pointer on the dial may be made in amperes. Again, the readings may be in volts for the potential difference between the ends of the strip or the terminals of the instrument. These instruments before you read to 2½ volts. They waste almost exactly *one watt* at their highest reading.

By inserting resistances of platinoid, or of German silver, we can increase the range of the instrument, but, of course, we expend more energy in such a case.

That there may be no creeping, or sub-permanent set or hysteresis, we find it sufficient before graduation of the instrument to keep sending a current greater than the highest which is to be used on the instrument for 72 hours, breaking and

voltmeter to 1,000 volts or more, the transformer being the only variable thing about it. I need hardly say that with several transformers and resistance coils at the side of this instrument, we may almost call it a universal instrument.

Note.—The above Paper is given as it was written in September last. When it was written the author felt certain of the constancy of the fatigued strips. Six months of further experience have since confirmed his views.

Added Later.—Fig. 3 shows our fuse arrangement.—T^1 and T^2 are the terminals of the instrument. Current flows from T^1 through the short thin copper wire T^1H, then through the adjustible resistance coil HD; then through the tightened platinum-silver wire DEC, whose ends are fixed, and which is kept sagged and tight by the metal spring HG; then through the twisted strip BA to the terminal T^2. But should the voltage between T^1 and T^2 be so great as to be liable to hurt the instrument, the wire DEC sags so much that the end G of the spring short-circuits the instrument through GH and the thin copper wire HT^1, the copper wire being instantly melted.

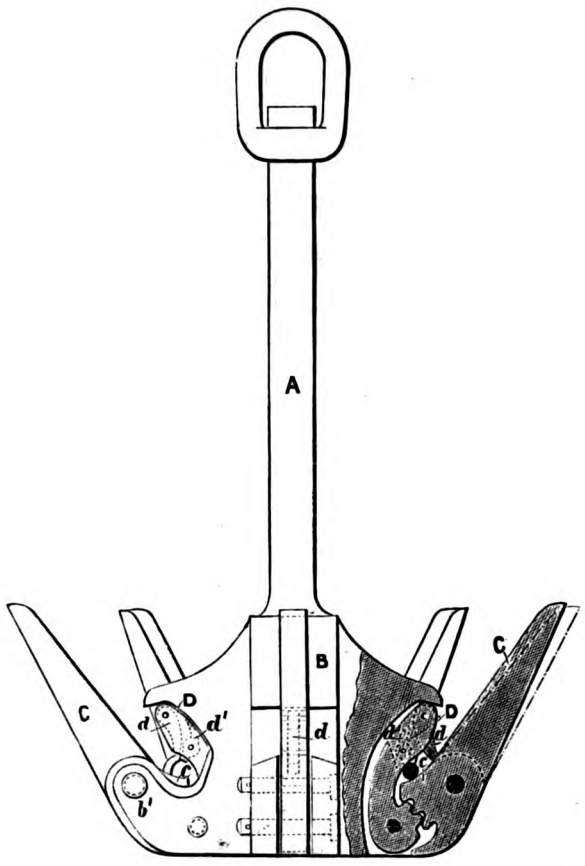
THE BENEST SUBMARINE CABLE GRAPNEL.

The object of this device, which is due to Mr. Henry Benest, of the Silvertown Works, is to provide a grapnel which will not merely hook a submerged cable, but will grip or hold the same fast when hooked. The essential feature of Mr. Benest's grapnel is the conversion of the flukes into automatically acting gripping jaws. The stem or shank of the grapnel is fitted with a boss which forms a guide for leading the hooked cable into the position to be gripped. Below this boss the shank is fitted with a thick plate carrying forked extensions standing out radially for the reception each of a fluke which is pivoted thereto. These flukes may be described as bell-crank levers, the short arms of which are intended to receive the pressure of the cable as it is caught, and thus cause the flukes which are in action to rise from their open position and close upon the cable, and grip it against the boss of the grapnel. By this arrangement it will be understood that the act of hauling in the grapnel will have a tendency to increase the grip of the grapnel upon the cable which it has caught.

The annexed figure shows in side elevation, partly in section,



The Benest Submarine Cable Grapnel. (Side elevation and section.)

one of these improved grapnels, fitted with a locking device. In this arrangement, instead of using the fixed gripping surfaces forming part of the boss B, a second movable jaw, D, is provided, which, like the fluke C, is pivoted within the sup porting arms extending horizontally from the boss. The jaws D are severally connected with their respective flukes C by interlocking teeth, which ensure the simultaneous approach of the jaws C and D to grip the cable when the pressure of the hooked cable comes upon the surface *c* of the tail of the flukes. Each jaw is slotted longitudinally to receive a locking pawl *d* and a tumbler d^1 situate below the pawl, and designed to move it into its locking position and retain it therein. These pieces, $d\,d^1$, are pivotally connected to the jaw D, and the end of the pawl, when in its locking position, enters a nick in the gripping face of the fluke C. The tumbler is so formed that, when not in action, its lower end will project somewhat from the gripping face of the jaw D, as shown on the left-hand side of the figure. This is for the purpose of enabling the cable, as it slides in between the gripping surfaces, to tip the tumbler d^1, and thereby bring into position the locking pawl *d*, as shown at the right-hand side of the figure. In order that the cable, whilst being hooked, may not be caught and lodge upon the top of the jaw-piece D, the cast boss is formed with a web which projects so as to cover the jaw-piece. The cable, it will thus be seen, being caught by the grapnel, and brought within the grip of the jaws C D, will be effectually prevented from escaping until released by hand after the recovered cable is suitably secured.

ON THE EFFECT OF TENSION UPON MAGNETIC CHANGES OF LENGTH IN WIRES OF IRON, NICKEL, AND COBALT.*

BY SHELFORD BIDWELL, M.A., F.R.S.

The *iron* used in these experiments was a piece of soft annealed wire, 0·7mm. in diameter and 10 cm. in length. The weights successively attached to it were equivalent to 1,950, 1,600, 1,170, 819, 585, and 361 kilos per square cm. of section. The *nickel* wire was 100mm. long, and 0·65mm. in diameter. The loads under which it was examined were 2,310, 1,890, 1,400, 980, 700, and 420 kilos. per sq. cm. The *cobalt* used was a narrow strip measuring 100mm. by 2·6mm. by 0·7mm.; its cross section being, therefore, 1·82 sq. mm. It was not possible to obtain this metal in the form of a wire. The loads employed for the strip were equivalent to 772, 344, and 75 kilos. per sq. cm. In all the experiments the loads were successively applied in decreasing order of magnitude, and before every single observation the wire or strip was demagnetised by reversals, without, of course, being removed from the coil.

The results obtained are shown in the curves in Figs. 1 to 4. Those in Fig. 3 are constructed from data obtained from Fig. 2; they show the magnetic contractions that would occur under increasing loads in constant magnetic fields of 125, 185, and 360 C.-G.-S. units respectively. These magnetic contractions would, of course, be superposed upon elongations of a purely mechanical nature, due to the tensional stress. In Fig. 4, for cobalt, the contractions corresponding to the various loads are indicated by different kinds of marks, and a single curve has been drawn as smoothly as possible through the whole of them. In all the figures magnetic fields (which are those due to the coil alone) are given in C.-G.-S. units, and increments and decrements of length are expressed in ten-millionths of the length (10 cm., or about 4 inches) of the experimental wire or strip.

Discussion of the Curves.

Iron.—The curves in Fig. 1 clearly show the effect of tension in diminishing the maximum elongation and hastening the contraction. With the two greatest loads used there was no preliminary elongation at all. The curve for an unstretched iron rod is generally found to cut the axis at about 300; probably, therefore, if the wire used in these experiments could have been tested with no load, its curve would lie a little above that for the load of 351 kilos.

Nickel.—The results for nickel are of great interest. In fields below about 140 units increase of load is always accompanied by decrease of magnetic contraction, the earlier portions of the six curves in Fig. 2 following one another in inverse order of the magnitude of the several loads. But, although the initial slope of the curves diminishes with increasing loads, the "turning points" where the ratio of the contraction to the magnetic field is a maximum occur later with great than with small loads, so that in a field of 360 the order of the relative values of the contractions for the three smallest loads is actually reversed, the contraction being greatest with the heaviest load and least with the lightest. It appears probable that, if the experiment had been carried far enough, the curve for 1,400 kilos would have crossed one if not all of the three curves lying below it. Whether the two remaining curves for 1,890 and 2,310 kilos would behave similarly is more doubtful. Possibly they would have become parallel to the horizontal axis before the others were reached.

I think it may fairly be assumed that if the experiment could have been made with the wire quite unstretched, we should have obtained a curve having a steeper initial slope than any of those in the diagram, but also reaching its turning point sooner, and therefore intersecting at least three or four of the others.

In Fig. 3 the results for nickel are presented in a somewhat different form, the curves showing the magnetic contractions of the wire under various loads in certain constant fields. The values for no load are taken from the results of an experiment with an unstretched nickel rod 0·3 cm. in diameter, and the portions of the

* Abstract of a Paper read April 24, 1890, before the Royal Society.

Digitized by Google

curves which depend upon the accuracy of these values are distinguished by dotted lines. It will be seen, however, that these portions are not of much importance. From these curves we at once see that in a field of 125 units, increase of load always causes decrease of magnetic contraction. In a field of 185, magnetic contraction increases as the load is raised from nothing up to about 700 kilos. per square cm., again decreasing with greater loads. And in a field of 360 units this singular reversal is exhibited in a still more marked degree, the maximum magnetic contraction occurring with a load of about 950 kilos per square cm.

The reversal phenomena observed in connection with the magnetic contraction of nickel are strikingly analogous to those which occur in the magnetisation of a stretched iron wire, and which are commonly associated with the name of Villari.*

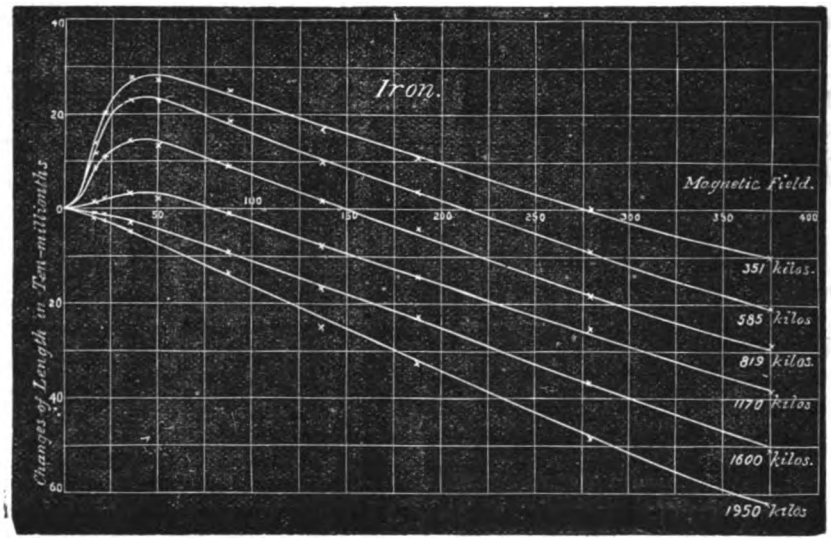


FIG. 1.

Prof. J. J. Thomson has shown† that the Villari effect is dynamically connected with the changes of length undergone by an iron rod when magnetised, an iron rod being lengthened in a weak magnetic field and shortened in a strong one. Now, cobalt behaves oppositely to iron in this respect, a rod of cobalt becoming shorter

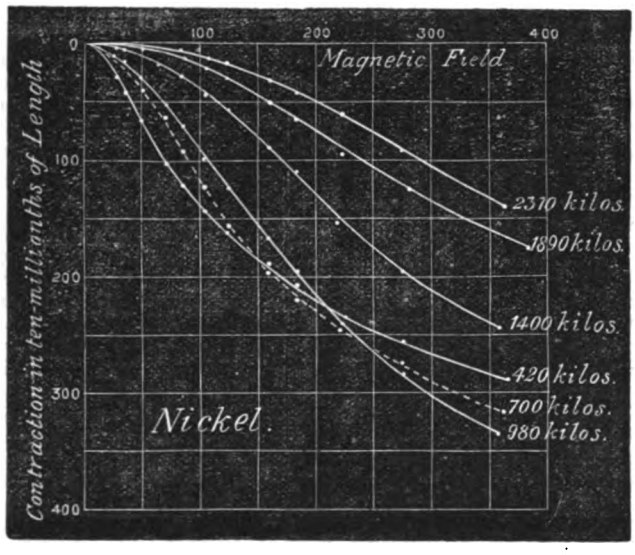

FIG. 2.

in a weak field, longer in a strong one.‡ Prof. Thomson, therefore, predicted that a Villari reversal would be found to occur in cobalt, and that it would be of the opposite character to that in iron. Some experiments made by Mr. Chree* with a cobalt rod under pressure gave results in accordance with Prof. Thomson's expectation.

But no reversal of the effect of magnetisation in diminishing the length of an unstretched nickel rod has ever been observed. Such a rod always becomes shorter in a magnetic field, whether strong or weak. It appears to attain its shortest length in a field of about 750 units, but it does not pass a minimum and become longer again in stronger fields, like cobalt. Applying Prof. Thomson's reasoning, therefore, to the case of nickel, we should expect that it would be found not to exhibit any Villari reversal, either of the nature of that in iron, or of that in cobalt. Both Sir William Thomson and Prof. Ewing have, in fact, looked for one and failed to find it. But in a Paper read at the meeting of the Physical Society on March 21, 1890,† Mr. Herbert Tomlinson gave an account of some experiments which, as he believed, showed that a Villari critical point really existed in nickel, though it was only to be reached by the application of comparatively great magnetising forces. I venture to suggest that Mr. Tomlinson's results may possibly be brought into harmony with Prof. J. J. Thomson's mathematics by consideration of the experiments described in the present Paper: for, as I understand Prof. Thomson's argument, he has hitherto

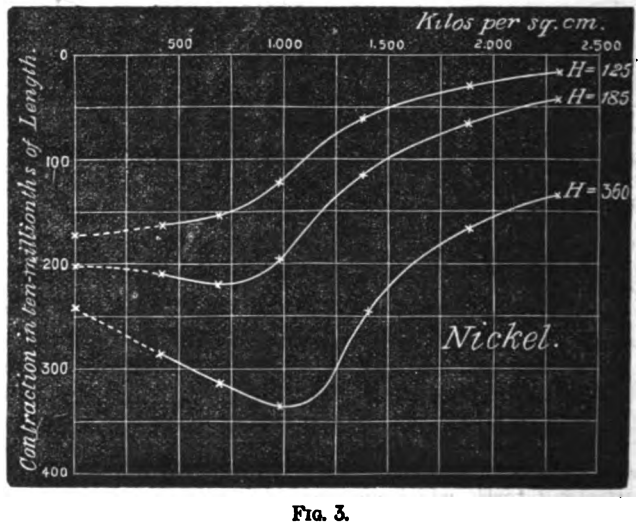

FIG. 3.

taken no account of the effects of mechanical stress upon magnetic changes of length.

Cobalt.—The results for cobalt show that the changes of length which this metal undergoes when magnetised are almost, if not entirely, unaffected by tensional stress, at least within the limits of the experiments. Having regard to the very marked influence of tension upon iron and nickel, this cannot but be regarded as a most remarkable fact.

* Poggendorff's *Annalen*, 1868. *See* also *Encycl. Britann.*, vol. 15, p. 269. When an iron wire subject to a magnetising force in the direction of its length is stretched by a certain force, the magnetisation of the wire is increased or diminished according as the magnetising force is less or greater than a certain critical value (depending upon the magnitude of the stretching force) for which stretching produces no effect.

Summary of Results.

Iron.—Tension diminishes the magnetic elongation of iron, and causes contraction to take place with a smaller magnetising force.

Nickel.—In weak fields the magnetic contraction of nickel is diminished by tension. In fields of more than 140 or 150 units, the magnetic contraction is increased by tensional stress up to a certain critical value, depending upon the strength of the field, and diminished by greater tension.

FIG. 4.

Cobalt.—The magnetic contraction of cobalt is (for magnetic fields up to 500 C.-G.-S. units and loads up to 772 kilos. per sq. cm.) practically unaffected by tension.

CENTRAL LONDON RAILWAY BILL.

HOUSE OF COMMONS.—THURSDAY, April 24th.

On Thursday, after the police evidence, witnesses were called as to the effect of the City and Southwark Subway upon the buildings along the route.

Mr. DOUGLAS YOUNG, Surveyor, of King William-street and Clapham, said that he had been engaged since the commencement of the City and Southwark Subway work in advising them professionally, and in purchasing the lands required for their scheme. He had also surveyed all the buildings along the line of route, and taken photographs of upwards of 500 buildings. None of the buildings along the line of route had had their stability affected. There had been some damage done where it affected the property facing the brick tunnels—some eight or ten cases. There had been no obstruction to traffic.

Sir SELWIN IBBETSON, M.P., gave evidence that he and some of his friends had deposited over £100,000 for the purposes of this Bill. He and his friends had gone very carefully into the whole matter, and they were satisfied that it would be successful.

Sir BENJAMIN BAKER was next examined. He said that he had been consulted with reference to big railways in Berlin, Vienna, Paris, and New York. He had carefully considered this scheme. Projects for railways along Oxford-street had been brought forward many times during the past 20 years, but it was only recently that he thought the time had been ripe for its being undertaken. A short railway of this type—a small tube driven by a shield—was constructed in New York 18 years ago, and was worked for two years as an experiment. But it was found that elevated railways were much cheaper, and they built them in lieu of 10 feet underground railways. The present scheme was the only plan in which future railways in the heart of London could be constructed. No one would ever allow an elevated railroad to be constructed, and an ordinary railroad, worked by locomotives, with all the ventilation blow-holes, would be impracticable on account of the cost. This line would be perfectly free from causing noise or vibration. They could attain a speed, including stoppages, of 14 miles an hour; and that would be more than two and a-half times as fast as a tramcar, twice as fast as an omnibus, and about one-sixth faster than the Underground Railway. There was no interference with the streets during the construction of the works. In that respect it differed entirely from the other underground railways, where the streets were broken up. Here there was no ventilating openings, and no interference with public convenience. He had not the slightest doubt that this railway, if constructed, could be successfully worked by electricity. The electric motor was as absolutely certain in its working as the telephone or the electric telegraph.

FRIDAY, April 25th.

On Friday, Sir BENJAMIN BAKER was recalled and further examined by Mr. Freeman for the Bill. Witness said that his experience in America of electric railways and tramways convinced him that they had passed beyond the region of experiment. There were 1,500 miles of electric railway constructed, and about 3,000 locomotives at work. In America they were subjected to very great difficulties and practical inconveniences from which they would be free in the Central London Railway. In America they had all the disadvantages of snow and frost, and the constant interruption from vehicles crossing the railway. Being in a tunnel the Central London was less difficult and less dangerous to work. With regard to the City and Southwark Railway, they had two types of locomotives, and a third was practically complete; each was an improvement on the other, and he thought they had arrived at practical perfection. In many of the electric motors gearing is used—steel-toothed wheels—and in others pitched chains; but we are proposing to work direct without any gearing or without any pitched chains. Therefore the electric motor that we shall use is an infinitely superior machine to an ordinary locomotive, and infinitely less liable to get out of order or to have any accidents.

Do you entirely agree with Mr. Greathead that in substituting iron tube stations for brick stations the danger of subsidence will be done away with?—There will be no risk whatever with the shields and iron-lined stations, but it involved a large additional expense. The precautions we have taken on this line in order to avoid damage to property, or any inconvenience to the pipes or otherwise, has involved a total expenditure of about £400,000. Cast-iron is adopted throughout. I was engaged on the Metropolitan Railway from Moorgate-street round to the Mansion House, and also on other lines in the metropolis. Compared with anything which was carried out on those Metropolitan Railways, the proposed works of the Central London Railway are insignificant. If we get amongst the sand and gravel we are prepared to work by compressed air; and then we can work as safely in gravel charged with water as we can in London clay. On the Underground Railway, when we were in wet sand and gravel, we pumped and dried the ground first by pumping.

Could you give us any information with regard to risks. The witness then read an abstract from an article by Mr. Sprague (*Electrician*, March 7, 1890, p. 443), in which the author said: "The objection raised by the municipal authorities in some instances on the ground of danger to life from the current may be met by the assertion that, although 80 lines are now in operation, and numerous shocks have been received by the *employés*, no serious injury has ever ensued; so that it may be safely asserted that a continuous current having an electromotive force of 500 volts is not dangerous to life. Grades of 12½ per cent. to 14 per cent. have been ascended by a motor car pulling a tow-car; in crowded cities the speed has been increased 50 per cent., and in the suburbs speed of 20 miles an hour are made."

Is it not the case that death has resulted in New York and elsewhere in the United States from electric wires?—Oh, yes; it happens very frequently. The tension is about 2,000 volts. I myself saw a man killed. He was upon a post changing a wire or doing something to a conductor, and he got the shock and fell down into the street. The Board of Trade have limited the tension in the case of the City and Southwark to 500 volts, and in another place to 600 volts.

Sir JOHN FOWLER was next examined in support of the Bill. In answer to Mr. Saunders, Q.C., witness said that he would pledge his reputation as an engineer that if they constructed the tunnel by a shield and iron tube they would practically get rid of all danger of subsidence. The experience with electricity in American railways is just as good as if the experience were gathered in London.

Does electric traction get over the difficulty of the impurity of the atmosphere?—You have perfect ventilation. Every train changes the air, and it comes in and goes out at the station by the operation of the working of the train itself.

MONDAY, April 28th.

On Monday, Mr. LITTLER, Q.C., opened the case for the trustees of the Paddington Estate, in opposition to the Bill. He said the property of his clients represented a money value of eight millions, and the fact that they were opposed to the Bill was a striking piece of evidence against the utility of the scheme to a portion of the district which it proposed to serve. He suggested that the promoters in thus seeking to push forward a scheme, of which the only precedent was one—the City and Southwark—as yet untried, were anxious to secure possession of the ground; and that they would in another Session come to Parliament for the alteration of their plans. The promoters of similar schemes, satisfied of the imperfection of their schemes, had withdrawn their Bills; and it was owing to the inherent badness of this scheme that competitors had determined to let it fall by its own weight. As to the proposed working of the railroad from a centre, that had been tried in other cases by ropes or atmospheric power, and had to be given up. Electricity had not been tried and was, he contended, impracticable. To compare the American street railways with the present scheme was as reasonable as to say that, because a watch went by a mainspring, you could work a railway by clockwork. Having regard to the entirely novel character of the scheme, the proper course would be to appoint a Select Committee or Royal Commission to inquire into this and similar modes of working, rather than a Committee who were tied down to the consideration of the one matter before them. Such had been the course when Parliament originally dealt with intercommunication in the Metropolis, and he asked the Committee to remember that Lord Derby's Hybrid Committee reported against a railway running down Oxford-street. To hand over the streets to the promoters for an indefinite time was an act of injustice to the owners of property; and Mr. Greathead, in his evidence, was bound to admit that, notwithstanding the greatest precaution, there was danger to buildings in his scheme. With the large capital sought for, and the enormous competition for traffic in the Metropolis, the scheme could never pay. For these reasons he submitted that the Bill should be rejected.

Mr. CHARLES GIBBONS, C.E., said he had visited the works of the Southwark Subway, and found that damage had been caused all along the line, especially at the stations. From an examination of the soil he apprehended similar damage if the scheme were carried out. As to

Digitized by Google

the proposed working he thought it unfair to tax that particular part of London round the Queen's-road generating station with the concentrated work for the whole length of the line; and he considered the generating station might, with advantage, have been taken much further west.

Mr. JEUNE, Q.C., addressed the Committee for the Ecclesiastical Commissioners and the Paddington Vestry. Having adverted to the improbability of such a railway paying its shareholders, he proceeded to deal with the question of construction and working. Although Sir John Fowler and Sir Benjamin Baker—perhaps the greatest engineers of the day—expressed their confidence in the undertaking, it was an undertaking wholly different in nature and working from anything in which they had been engaged before. Great engineers had erred before now, and the eminence of the two gentlemen in question did not afford that safeguard which it would do if the matter was one in which they had had real experience. This railway was an electric railway, or nothing; and on this he pointed out that as to the cost of working there was nothing but the guess of Mr. Mather that it could be done for 9d. If the promoters had only waited until the City and Southwark was opened, the cost would have been perfectly well known, and this important question solved. As to the loss of power in working, they were absolutely at sea, and the two leading witnesses for the promoters were entirely at sea on the subject. Dr. Hopkinson said that the loss would be about 33 per cent. Sir Benjamin Baker, speaking of American railroads, said the loss was about 50 per cent.; and it was put to another witness by Mr. Littler that when you got to actual experiments on a railway for the purpose of testing the motors, the loss rose as high as 85 per cent. And this was against a loss of 15 per cent. in the case of steam. There, then, was a matter of vital importance in which the Committee was left in the dark. The information afforded on other matters, too, was so scanty that he urged it contained no justification for the Bill.

TUESDAY, April 29th.

Mr. JEUNE, Q.C., further proceeded to address the Court on behalf of the Ecclesiastical Commissioners; and Mr. Cripps, Q.C., was heard on behalf of Lord Portman, the vestry of Marylebone, owners of property in Oxford-street, frontagers in Holborn, and owners and occupiers of frontages on the City portion of the line. The first point put forward as a basis of opposition was that there was no case of public necessity for the line from a traffic point of view. The learned counsel went on to contend that the tendency of traffic was to increase by means of overground conveyances, such as omnibuses and trams, rather than by underground railways; and the increased number of passengers travelling by the Metropolitan and District Railways was no proof of the necessity for this line. He would also say that the experience in connection with other electric railways did not bear out what had been put forward by the promoters as to the expense, and contended that it would be impossible to work this line on a remunerative basis. As regards what had been said about the fact of there being electric railways working in America being a justification for such a line as this, one might just as well go to America and say that because a Committee in this country had sanctioned the City and Southwark Subway that was a justification for the adoption of the same system in America.

Mr. Edward White, Chairman of the Parliamentary Committee of the Marylebone Vestry, Mr. James Marshall, and others, were then examined.

WEDNESDAY, April 30th.

Mr. WILLIAM BOURNE LEWIS, M.Inst.C.E., examined by Mr. Pope, Q.C., said he had had considerable experience in the construction of railways and other public works. He did not think the proposed railway could be constructed in Cheapside or the Poultry without damaging the buildings. The risks were real to such important buildings as St. Paul's Cathedral and large warehouses and business premises. The fear of disasters from the construction of such railways as this had been increased after an inspection of the City and Southwark Subway, where considerable damage had been done, notwithstanding that great skill had been shown in the construction of the line. He feared that damage would be done to Bow Church; it was his opinion that the driving of the tunnel might cause subsidences along the line of route, and he anticipated injury to the Mansion House. As to Messrs. Mappin and Webb's premises, it was quite possible that the whole building might come down. The National Safe Deposit Company's premises were founded at a depth of 42ft., and then a layer of concrete 6ft. in depth had to be placed there before the building could be built, owing to the indifferent state of the subsoil. He submitted that the risks were so real and the injuries that might result so serious that further experiments should be made before such important thoroughfares were handed over to the promoters. No tunnel had been made in the London clay at a depth of 100ft. without subsidence resulting. In saying this he had in his mind brick tunnels. When the Metropolitan Railway was constructed along Cannon-street the houses there were all underpinned. He had had considerable experience in America, and he knew the tunnel under the Hudson River, in the case of which the water had broken in on more than one occasion, and several people had been drowned. Personally, he would like to see this scheme carried out; but he did not consider that it would be safe, in the present state of engineering experience in these matters, to carry out this line. It was merely an experiment.

Cross-examined by Mr. Saunders, Q.C., he still persisted in that assertion, in the face of the successful experience in the case of the Sinclair Tunnel under the St. Lawrence and the City and Southwark Subway in this country. He did not know that in the latter case some of the cracks which were attributed to the subway were found to have existed before.

Further evidence having been given by Mr. JOHN BELCHIER, architect and Mr. R. T. KINGHAM, the secretary of the London General Omnibus Company,

Mr. BIDDER, Q.C., proceeded to address the Committee on behalf of the Duke of Portland in opposition to the Bill.

THURSDAY, May 1st.

Sir JOHN FOWLER having been recalled and further examined by Mr. Pember, Q.C., as to the estimates,

Mr. ALFRED LYTTELTON proceeded to address the Committee on behalf of the Duke of Westminster in opposition to the Bill. This line had been put forward by Sir Benjamin Baker in the light of his experience of electric lines in America; but he admitted that he was not an expert in electrical matters, and left the details of the system to be dealt with by Sir John Fowler; but when he came all he did was to produce the advertisement sheets of certain railways in America, and no American engineer had been called to speak to the practical working and expense of the electrical lines there. A great source of danger in the present case lay in the fact that there was to be only a single generating station.

Mr. P. C. CLARK, F.R.I.B.A., surveyor to the Fishmongers' and Cordwainers' Companies, then gave evidence in support of the case of the Duke of Westminster, and described the character of his property, much of which, he said, had been rebuilt at a cost of £70,000 to £80,000.

THE RAILWAY RATES INQUIRY.

The Board of Trade inquiry respecting the proposals of the railway companies for the classification of merchandise traffic under the provisions of the Railway and Canal Traffic Act of 1888, was continued on Friday last before Lord Balfour of Burleigh and Mr. Courtenay Boyle, C.B., the Parliamentary and Assistant Secretaries of the Board. The traders' proposals in reference to Class 2 were under consideration.

FRIDAY, April 25th.

Electric Cables.

Lord BALFOUR OF BURLEIGH asked if it was agreed that electric cables should be inserted in the classification as hardware.

Mr. R. H. TWELVETREES (Great Northern) objected on behalf of the railway companies, but said they were included in the list which the traders wished to have included as hardware.

Mr. IMPEY asked the Court to allow the item to be struck out as far as the Birmingham Association were concerned. It had been put in under a misapprehension, and the traders had no wish to advance any arguments in favour of the proposal which had been submitted.

Lord BALFOUR OF BURLEIGH: Do not the electric and the allied trades appear upon this?

Mr. HOWELL, who represented the traders generally, replied in the negative. The objections of the electric and allied trades would come on in a subsequent class.

Electric Insulators.

Mr. COURTENAY BOYLE asked if electric insulators were hardware.

Mr. IMPEY said that was another point which the traders did not wish to press. These electric articles had been put in under a misapprehension.

LORD BALFOUR OF BURLEIGH asked if electric insulators were classed at all.

Mr. TWELVETREES said they were in Class 2, under the heading of electric accumulators.

Mr. COURTENAY BOYLE said an insulator was not the same thing as an accumulator.

Mr. WILKINSON said they would be charged under the head of earthenware.

Mr. COURTENAY BOYLE said he knew enough about electric insulators to know that they need not be earthenware or china or anything else.

Mr. TWELVETREES said they were in Class 2 of the clearing-house classification. Electric insulators, glass, were in Class 2; and telegraph insulators, packed, in Class 1. The companies had adopted the term electric insulators to cover the two, and had put them in Class 2.

Mr. COURTENAY BOYLE: And that is meant to cover the little bobbins, if that is the proper phrase, which guard the wires on the posts? Is that so?

Mr. TWELVETREES: Precisely.

Mr. COURTENAY BOYLE: If you are satisfied, well and good; but electric insulators mean other things besides that.

Mr. IMPEY repeated that, so far as the Birmingham Association were concerned, they did not press their objections with regard to either of these items.

TUESDAY, April 29th.

Telegraph Insulators.

On Tuesday the classification of "telegraph insulators" was considered.

Mr. A. P. TROTTER said he had to object, on behalf of the Electrical Trades Section of the London Chamber of Commerce, to the omission of this item. The objection of the railway companies was that they should be classed with electric insulators in Class 2. "Electric insulators" was a vague term, and he could not say what it meant; but "telegraph insulators" was a well-known term, which it was scarcely necessary that he should describe. Telegraph insulators were generally made of earthenware,

Digitized by Google

and they were sent out with the spikes fastened in, forming a rather heavy article. It was in the Railway Clearing House classification in Class 1. He thought they were always packed, and he had nothing to say except with regard to packed insulators. The traders objected to their being put with electric insulators, which were commonly made of glass. In America they were of glass, but in this country earthenware insulators were always used for telegraph work, and the article was packed in casks.

Lord BALFOUR OF BURLEIGH: If you put in the words "telegraph insulators" would it not affect insulators in Class 2, and would not the makers of electric insulators, which you say are of glass, claim to come under "telegraph insulators"?

Mr. TROTTER: Glass insulators are not used in this country by reason of the climate. In this country earthenware insulators only are used.

Lord BALFOUR OF BURLEIGH: Although glass insulators are not used in this country, it may be that they are made in this country and sent elsewhere.

Mr. TROTTER: We should have no objection to have "telegraph insulators, not glass, packed." That would satisfy the conditions.

Mr. HARRISON, for the railway companies, said that what the companies knew as telegraph insulators were the small earthenware blocks; they had no objection to place "telegraph insulators, earthenware, packed," in Class 1.

Batteries, Packed.

Upon this item, Mr. HOWELL, solicitor, said the electrical trade were satisfied with the railway companies' explanation. They would stand in Class 3.

Dynamos and Electrical Machinery, Packed.

Mr. TROTTER: In this case, also, we accept the replies made by the railway companies. They are not included in the classification. They go as machinery. We objected to the omission, but we accepted the explanation that they will go as machinery.

Electric Storage Batteries.

Mr. TROTTER: We also accept the replies of the railway companies in this case.

ELECTRIC LIGHTING AT BRIGHTON.

LOCAL GOVERNMENT INQUIRY.

On Tuesday last Mr. Codrington, M.I.C.E., commenced an inquiry at the Town Hall, Brighton, on behalf of the Local Government Board, into the application of the Corporation to borrow £32,500 for the purposes of electric lighting and £4,500 for the purchase of land for a storeyard. Mr. Boxall appeared for the Town Council; Mr. Sutton opposed on behalf of a number of ratepayers representing a rateable value of £272,000; Mr. G. J. Castle, Q.C., opposed on behalf of the Brighton and Hove Electric Light Company; Mr. H. J. Verrall opposed on behalf of Colonel Tamplin, Mr. G. Attree, and Mr. G. F. Attree; Councillor Blaker said he opposed as a member of the Town Council.

Mr. BOXALL, in opening the case for the Corporation, said the Corporation of Brighton had carefully watched the progress of lighting by electricity for the past ten or twelve years. So far back as 1879 or 1880 they carried out experimental works. In 1881 they had a large part of the Marine-parade lit up by Siemens Brothers. In 1881 and 1882 the Pavilion and Dome and Corn Exchange were lit by the British Electric Light Company and the Brush Electric Light Company. In 1882 the Corporation obtained a Provisional Order, and it was under that Order, with some modification, that it was proposed to supply the town with electricity. In 1883 a small installation of about 400 lights was made at the Pavilion, and in 1884 that was extended to the Dome Assembly Room and Free Library. In 1884 they obtained a report from Dr. Gooch as to lighting the Front. In 1886 and 1887 the work at the Pavilion was taken down and relaid with extensions, and that installation was now in full working order, and was now in the hands of the Corporation. In 1889 the Company, which had been supplying some part of Brighton with overhead wires, having no statutory powers whatever, gave notice of their application for a Provisional Order. The Corporation withheld their consent. An inquiry took place in April, and in May a correspondence took place between the Board of Trade and the Corporation, in which the Corporation stated that within two years they would put their electric powers in force. In pursuance of that undertaking the Corporation proceeded to get the best advice as to the lighting. They got a report from Mr. Shoolbred. On December 31st he made a report, and on January 23rd it came before the Town Council, and a resolution was passed which was the basis of that application. That resolution was confirmed by a special resolution, arrived at on March 3rd, 1889, as to an increase of area. As regarded the loan, the rateable value was £664,048. The sum borrowed must not exceed £1,328,096. The present debt was only £263,575, so that there was a margin of £1,064,000 available to the Corporation at the present time.

The INSPECTOR said he should like to know from the Town Clerk whether the debt on the Waterworks was included in this.

The TOWN CLERK said this was under a special Act of Parliament. The debt was about £500,000.

The MAYOR (Alderman Manwaring), examined by Mr. Boxall, said that during the past 10 years the Corporation had been directing its attention to electric lighting. They had consulted a number of engineers, and had made several experiments; but they thought the time had now come when they should undertake the lighting of the town. They had made close inquiry as to the cost and prospects of the installation. They had obtained reports from more than one engineer, and he felt morally certain that the works would soon require extension. From what he knew he considered it important that the Corporation should themselves have the control and the laying down of the electric wires and the supplying of the light in the town.

Cross-examined by Mr. CASTLE as to whether he thought it fair that the Brighton Company having done the work well for nine years and benefited the town, the Corporation should come in and take the business just when they thought it likely to be a commercial success, without compensation.

The MAYOR said he was of opinion that the Company had no right to any compensation.

Mr. SUTTON then produced a petition, which he said had been signed by 10,000 ratepayers, against the Corporation undertaking the electric light.

Mr. J. G. SHOOLBRED was then called. In his opinion the system best suited for the requirements of the district was the low-pressure system with continuous current, supplemented by storage batteries. The system was in use in London at Kensington, at Chelsea, at Westminster, at St. James's, Pall Mall, and also in the provinces at Liverpool, Leamington, Bradford, and possibly at other places. So far as he knew, the results in these places were satisfactory. The installation proposed for Brighton would light 5,000 sixteen-candle lamps at one time, and 10,000 lamps would be attached. The total cost he estimated at £30,000, and he thought the installation would be sufficient for the present requirements of the extended area, while it would also admit of extension without difficulty if there were a larger demand. He was aware it was contemplated to charge 6d. per unit, and he recommended that charge himself.

Mr. CASTLE: It has been suggested by our own witnesses that £6,000 ought to be put down for the buildings, and not £3,000; and that when the Corporation put them up they will cost nearly £10,000.—I should be surprised if they did.—Witness: continuing, said he had calculated that 5,000 lamps would use 402,000 units.

Mr. CASTLE: Would you be surprised to hear that we have 5,000 lamps installed as compared with your 10,000, and they only produce 127,000 units?—I should.

Can you give me the figures on which you get the 402,000 units?—The figures are detailed above in the report.

Mr. CASTLE: Can you tell me what distance you can work from your station on this system?—It depends on the pressure to which you limit yourselves, and what you put into your mains.

Can you work a mile or three-quarters of a mile?—A mile is a long distance to work a feeding main.

Cross-examined by Mr. VERRALL: He had made no estimate of the numbers of persons or houses likely to use the electricity. He should consider that on an average 80 to 100 lamps would be used in each house.

Mr. R. E. CROMPTON was then called. He believed that under the existing circumstances the Corporation were wise in undertaking the supply of electricity for themselves. He thought the work might be undertaken with safety at the present time. He thought £30,000 sufficient for the installation, and he generally approved of the scheme and the figures. He considered the low-pressure system most economical, as by it they were able to lock up the central station at midnight, and work with two shifts of men in the winter, and one in the summer, instead of three all the year round, making a considerable saving in labour. The main feature in the price at which the unit could be supplied would be the amount of consumption, as there was so much fixed expenditure. As to the renewal of plant, after careful consideration, and after taking the opinion of several gentlemen, and with a Committee including Sir Frederick Bramwell, they fixed on the plan of setting aside every year a certain percentage on each class of plant, and from that deduct any sum that happened to be paid for repairs during the year, and carrying the balance over.

Cross-examined by Mr. CASTLE, the witness said he did not understand that for the purpose of rating it had been decided by an Act of Parliament applying to the Metropolis that 33 per cent. should be allowed for the depreciation of buildings and machinery. He thought 4½ per cent. sufficient. For machinery made of cast-iron or something of that sort 10 per cent. might be written off for depreciation, because the original cost was low; but a dynamo was a very expensive machine, and therefore the repairs bore a small proportion to the original cost. For 5 per cent. on cost price makers would keep engines in order for ever. At Chelmsford the witness mentioned that his firm was trying to get 1s. a unit for private lighting, and they were getting about 2d. a unit for public lighting. They gave the public light practically for nothing in order to get the private lighting. The average cost of public and private lighting put together would be about 7d. per unit, which would about cover the expense. He should have thought that if the Brighton and Hove Company had been supplying the place well they would have had more custom. He would naturally feel strongly upon the matter if he had been supplying a place for eight or nine years, and the Corporation then stepped in; but as to whether it was right or not for the Corporation to do so was another thing. As to whether the electricity could be supplied at 6d. per unit must depend upon the consumption. He should estimate that 100,000 units could be supplied at 7·69d. per unit. He did not think there was any sinking fund for replacement, but if there was it would have to be added, and if the electricity could not be supplied for the money which was proposed to be charged, the deficit, he presumed, would have to be made good out of the rates. He supposed the Corporation considered there was a demand for the electric light beyond the customers of the present Company. He had always understood that there had been a great demand for the electric

Digitized by Google

light in Brighton. He should think shops would use it at 7d. per unit. It was comparable to gas at that price.

In answer to Mr. VERRALL, the witness said that about 50 lamps on the average would go to a house, so that the Corporation would supply about 200 houses.

Mr. ALEXANDER SIEMENS said he had considered the system of supply which the Corporation proposed to adopt, and he thought it was one which was best adapted to the circumstances in Brighton. His firm had tendered upon the specification of Mr. Shoolbred.

Cross-examined by Mr. CASTLE, the witness said that he did not know sanction had not been obtained for the borrowing of the money when he tendered. He thought the work could be done for Mr. Shoolbred's estimate, and if the Corporation would give him the order now he would take it.

Mr. CASTLE: And keep it in repair for ever at 5 per cent.?—I believe 5 per cent. on £30,000 would about cover it.

Continuing, witness said that he had gone into the estimate to see whether the undertaking would pay or not. He had allowed 5 per cent. for renewal fund, and 5 per cent. for repayment of capital, and 10 per cent. for depreciation of machinery. Those three items amounted to £3,800. Then he put labour at £1,700; coal (25s. per ton), £1,500; sundries, £300. These items amounted to £3,500, against Mr. Shoolbred's £4,290.

Mr. CASTLE pointed out that Mr. Shoolbred had items amounting to £1,990, against the witness's £800, and that Mr. Siemens had not made an allowance for rates and taxes. The witness said that on his estimate 4d. a unit would pay, so that left a good margin. He had based his estimate on the assumption that 400,000 units a year would be used. He at the same time admitted that he had only allowed 1½ per cent. for repayment of capital.

This concluded the evidence on behalf of the Corporation.

Mr. T. A. GOODMAN, solicitor, Brighton, gave evidence to the effect that he was engaged on behalf of various ratepayers, that he received instructions from Mr. Joseph Wood, and produced a petition signed by 10,000 ratepayers.

The inquiry was then adjourned until Wednesday morning.

WEDNESDAY, April 30th.

On the inquiry being resumed, Mr. CARPENTER, an ex-member of the Town Council, addressed the Inspector, protesting, as a ratepayer, against the line pursued by the Town Council, contending that they were not justified in placing a heavy burden on the town for the supply of a little district.

The matter of the petition presented the previous day was then gone into.

Mr. BOXALL said they had given their attention to the petition, and, selecting the eleventh sheet from the end, had made a careful investigation. On that sheet there were 26 names on each column. On the left-hand column 12 were names of persons on the rate-book and 14 names not on the rate-book. It was represented to be a petition of 10,000 ratepayers. There were 176 sheets of it, and room for 52 names on each sheet, so that even if all the sheets were full, as they were not, there could not be 10,000 on the petition.

Mr. SHOOLBRED, who was recalled, said he estimated the average consumption on weekdays at 20,800 hours.

Mr. CASTLE, addressing the Inspector on behalf of the Company, said they were there because they had been providing the electric light in Brighton for years, and because they thought the Corporation were treating them unfairly and ungenerously in now attempting to come forward and to a certain extent take away the business which the Company had built up. He commented on the fact that the Corporation had done nothing since they obtained their Order in 1883. The Company, however, stepped into the breach, and supplied what was the cheapest and most economical form of electric light for a large area. Contrasting the two systems, he claimed that the alternating system as adopted by the Company was the best. Mr. Castle urged that the Corporation were going into an expenditure of £30,000 when the undertaking could not pay expenses. He asked the Corporation to delay the work until November, when the opinion of the ratepayers could be obtained. Dealing with the question of overhead wires, he said the Corporation refused to meet them in any way, and that was the reason the Board of Trade refused the Provisional Order asked for by the Company so as to enable them to put them under the ground. The Company, said Mr. Castle, had actually been led on by the Corporation from time to time to do their work, and now the Corporation refused to meet them in any way. He contended that the evidence failed to show that the Corporation were acting with the general consent of the inhabitants, and claimed that they ought to have called a public meeting.

Mr. W. LOWRIE, consulting engineer to the Brighton and Hove Electric Lighting Company, said that 10,000 lamps would not use as much as 402,500 units per annum.

At the close of this evidence the question of the petition again cropped up, and Mr. TALBOT stated that on page 7 there were 25 names on one side and 26 on the other. Of the 25 names seven were not on the rate book, and of the 26 there were four not on the rate book.

Mr. SUTTON then addressed the Inspector, urging that the ratepayers had no opportunity of expressing their views upon the question whether the Corporation were or were not to carry out the electrical power conferred upon them by Parliament. He described the scheme as a very risky one, especially as in order to succeed it would be necessary to cut out the present Company.

Mr. BOXALL next replied on behalf of the Corporation.

The inquiry then closed.

CORRESPONDENCE.

LIGHTNING IN ELECTRIC LIGHT LEADS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The enclosed letter from a correspondent in Portugal reached me shortly after the recent meeting of the Institution of Electrical Engineers, where I had been surmising that such occurrences might be not uncommon. Although the damage done was only slight, the account is perhaps of sufficient interest for insertion in your paper.—Yours, &c.,

Liverpool, April 26, 1890. OLIVER J. LODGE.

(COPY OF LETTER.)

Companhia de Luz Electrica, Oporto, Portugal, April 19, 1890.

To Prof. Oliver J. Lodge, University College, Liverpool.

SIR: Though personally unacquainted with you, I take the liberty of sending you a specimen of a lightning-injured wire, and a statement of the circumstances which seem to me to go to confirm your views on the lightning-rod question.

The electric light system here is operated by means of both overhead and subterranean wires on the low-tension direct system, and the station stands well in the middle of the city and its district, in a roughly pentagonal space bounded by five streets.

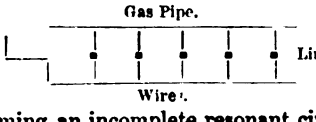
About 9 p.m., on the night of April 17th (Thursday last), a severe flash struck apparently into this space; but, dividing between many telephone wires two or three lightning conductors and tall houses very wet from four days' nearly continuous rain, did no structural damage. The report in the electric light works followed instantaneously after the flash. Nothing was observed on the lightning protectors of the lines, and no damage was done to any part of the apparatus or machinery.

But two faults were caused in installations within 100ms. of the works, the wire I enclose being one. In this case the shop is supplied from an overhead line. The damaged wire was inside a tubular arm on a "combination" (gas and electric) pendant, and the pendant gave a good earth through gas pipes. The people in the shop say that the lamp gave two sharp cracks and then went out. The lamp, however, was not damaged. It merely went out because the discharge ruptured the wire. No other wire or lamp in the shop was damaged, and the faulty wire was at the extreme end of the shop, as far from the entrance of the leads as could be—perhaps 8ms. or so. The brass tube enclosing the wire showed no injuries externally. One end of the wire earthed on the pipe, and the fault was detected by the insulation test of the following morning, before any complaint reached me. The overhead line runs very low, and is crossed by many telephone wires at up to 10 or 15ms. greater altitudes.

The other case occurred in a shop connected to the underground line. A spark passed between an electric bell wire and a twin wire leading to a single lamp, at a spot where the bell wire crossed the light conductor. All these wires, the P. and N. light conductors and the bell wire, were ruptured, the bell wire losing about 1cm. by volatisation or fusion. The insulations showed no signs of overheating, and the fuse wire in the cut-out was not fused. Surrounding woodwork was slightly scorched and smoked at the point of rupture of the wires.

This case is rather curious. The bell wire and its circuit is wholly within the house. The electric lighting line is entirely underground, and no discharge could have got into it from an overhead line without passing through the works and running the gauntlet of two lightning protectors, one on each line terminal. A telephone wire runs near the bell circuit inside the house, and this wire got some discharge, the aerial line parting outside the house, and the instrument being rendered useless.

Does it not appear probable that the spark which passed between the bell and the light wire was due to an induced current set up in them, or perhaps to a resonance effect? It seems impossible that any direct lightning discharge can have got at either circuit, at least without leaving behind it unmistakable traces. And in the first case, though not clearly impossible, it seems to me improbable that any part of the actual flash reached the line, it being so well protected by the higher network of telephone wires. Also any lightning flash would pretty certainly have done much more damage, and would hardly have picked out the last pendant in the shop to burst through in. In this case the main gas pipes run down one side of the shop, the electric light wires down the other, thus in plan—



perhaps thus forming an incomplete resonant circuit, of which the fault formed the spark gap.

Digitized by Google

On the same night, probably a few minutes later, a flash struck near or actually on to a small theatre lighted from our circuit. This theatre is roofed and walled with galvanised iron, so that any entry of a flash would seem impossible. But a lamp in the manager's office burst: short-circuiting across the platinums inside at the moment of the flash. This is an accident that sometimes, but rarely, occurs to a lamp at normal pressure; nearly always, however, to new lamps, whereas this lamp was old. It happens that the lead and return of this particular lamp do not run together, but form a loop; in fact, the lead comes off one circuit, and the return off another, the two circuits being in separate casings, parallel, about 3 or 4ms. apart. Might this have been another case of a resonant circuit? Anyway, something raised the potential difference between the two wires considerably at the moment.

No complaint has been received from any other installation on the same circuit, and its insulation was normal on the following morning. It is, I should say, an overhead circuit, about 350ms. in length, the theatre being at the far end from the works.

My apology for troubling you must be the interest you have shown in collecting information as to lightning effects; and the reiterated complaints of those who study the matter of the difficulty of getting such information untinctured with optical illusion effects, and so on. I could tell you of some wonderful things seen in shops, &c., lighted by us, on the occasion of this flash (which was most startling); but I did not notice anything of the kind, and rather doubt whether anyone who caught the full light of the flash could know for a minute after whether the lamps burnt blue or green; or, indeed, whether they were alight or out.

If these slight remarks are of any value, you will please put them to any use you see fit. H. M. Sayers.

ELECTRIC WELDING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your editorial on "Welding by Electricity" in last week's number you say, "Strangely enough, though this fact has been known so long, it does not seem to have occurred to any single soul, until three years ago, that if for the two carbons there were substituted two pieces of metal, and an end pressure applied, the two metal rods would become welded together."

Permit me to inform you that I, and doubtless numerous other persons, saw electric welding done more than twenty years ago by a "Wilde" machine. I myself welded a tang upon a file with but slight blistering at the junction.

Mr. Wilde's patent, No. 1,412, of 1865, expressly mentions the application of his machine to welding, but he does not appear to have brought it into practical operation.—Yours, &c.,

17 and 18, Cornhill, E.C., April 26, 1890. F. Higgins.

THE DIATHERMANCY OF AIR IN RELATION TO THE EFFICIENCY OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of the 18th inst. there is an abstract of a Paper read before the Institution of Electrical Engineers by Mr. Higgins on "The Diathermancy of Air in relation to the Efficiency of Incandescent Lamps." This contribution contains nothing new, nor do I see any additional reliable practical results therein, beyond what have been already published. The results Mr. Higgins has obtained with his three lamps, and by using a thermopile for his purpose, could have been obtained by a practised person using his bare hand for the test; and a person could have separated these three particular lamps according to their order of exhaustion.

I should be inclined to think that diffusion and convection have, in at least two of the cases, more to do with Mr. Higgins' results than diathermancy had.

In the same Paper he says, he has not seen or heard of any previous mention of this property as affecting incandescent lamps, &c. Diathermancy, *i.e.*, the permeability of the surrounding medium to radiant heat, is directly recognised when using the well-known hand test, and the varying effects on the efficiency of lamps caused by imperfect exhaustion have been long known to lamp-makers and used as a rough test of the state of exhaustion.

Mr. A. Bernstein published an article in the *Centralblatt für Electrotechnik*, and *Industries*, March, 1889, showing the energy per unit of surface required to maintain a dull red glow (526° C.) when using platina wires enclosed in a medium at various pressures, from 760mm. down to his best obtainable vacuum. Also, Mr. Swinburne, in his Papers on lamp manufacture, a year or two ago, in the *Electrical Review*, pointed out that the observation of excessive warmth was an indication of bad exhaustion.

The practical use of this property as a test of the minute differences in the vacua of carefully made glow lamps does not seem to hold out promise of any reliable results, and to me it seems not such a simple matter as Mr. Higgins would imply. For instance, the differences in the state of exhaustion between two carefully made lamps, which have been already tried by the coil test, are in any case far within the $\frac{1}{10}$th inch Mr. Higgins gives; and these differences are of such a fine order as to be immeasurable when compared with the differences likely to have arisen in the measuring, firstly, of the surfaces of the filament, and secondly, of the electrical power converted therein. The coil test can only by great care and exact observation of results be made fairly satisfactory; and one would therefore still wish for a test which would not want so many precautions, and would quickly show comparative states of exhaustion, not within $\frac{1}{10}$th inch, but $\frac{1}{10}$th millimetre at most. With the coil test, and however performed, lamps will give a negative result both with perfect vacuums and very imperfect ones; but such lamps, if mixed together, can be readily separated by incandescing them and using the hand-test.

Mr. Higgins also remarks that lamps with a perfect vacuum attain and lose their incandescence slowly when the current is applied or removed, while those lamps having an imperfect vacuum start suddenly into incandescence and as suddenly lose it. Although this may be quite true of similar metallic filaments, yet, on the other hand, with carbon filaments, both these effects may be simultaneously obtained by placing two carbon filaments in the same bulb, but one of which filaments varies somewhat from the other, either in specific resistance or condition of surface. By taking two such filaments, one having a high specific resistance and the other having a low specific resistance, and both having similar surfaces, giving the same candle-power and requiring the same number of watts per candle-power; then, by simultaneously applying and removing the current to these two filaments and when enclosed in the same medium, it will be seen that Mr. Higgins' statement has, at least, reservations, and has no practical signification; for the carbon of low specific resistance will slowly increase in incandescence and as slowly lose it, while the carbon of high specific resistance will suddenly increase in incandescence and as suddenly lose it.—Yours, &c., C. J. Robertson, A.I.E.E.

COMPANIES' MEETINGS & REPORTS.

Indo-European Telegraph Company (Limited).

The twenty-third ordinary general meeting of the members of this Company was held on Monday, at Winchester House, Old Broad-street, under the presidency of Mr. J. Herbert Tritton.

The MANAGING DIRECTOR (Mr. W. Andrews) read the notice convening the meeting, the seal was affixed to the register of shareholders, and the report of the Directors was taken as read.

The CHAIRMAN: I now beg to move—

"That the report and accounts now submitted be received and adopted, and that a dividend be and is hereby declared for the half-year ended December, 31, 1889, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year."

In moving that resolution, gentlemen, you will permit me to draw the attention of the proprietors to the working of the Company in the past year. The results of the working, as you have already seen from the report, are much the same as for the previous year. The receipts are fractionally less, by the sum of £2,038. The expenditure on commercial account has been practically the same, with variations in the details; but when we come to maintenance account the expenditure has been materially more, and shows an increase of the considerable sum of £6,819. This, you will be pleased to hear, is attributable solely to additions and improvements on our line. In view of this expenditure we carried forward, as I daresay you remember, from 1888 to 1889 the sum of £6,783, and, if I remember right, we told you that that would in all probability be absorbed. The forecast made by our good friend Mr. Andrews was singularly accurate; for the additional expenditure during the year has been almost precisely that amount, as you will have noticed from the accounts. During the year now current we shall also have to face an extraordinary expenditure in maintenance account, though not at all of the same serious nature. The sum will depend very much on the amount of work which we can put through during the year. It is impossible to say how much the expenditure will be; but I think I may, without much fear of the event belying my word, say that it will not be an amount at all likely to affect any dividend which may be earned. We are still face to face with the fact that the decreased revenue from messages exchanged with India, to which I adverted at some length last year, goes on. This has followed upon the reduction of tariff which took effect upon July 1, 1886, since when the receipts from this source have shown a continuous decline of a serious character. I should like to put before you the statistics of the gross receipts of Indian messages for the last five years. In 1885 the amount was £394,270; in 1886, the year when the reduction of tariff was made, the amount was £374,122; in 1887 it was £342,272; in 1888 it was £334,129; and in 1889 it was £328,490. I think I am not wrong in saying that that decrease is of a serious nature. The result is the more extraordinary because the imports and exports of India have not shown, I am pleased to say, the same unsatisfactory figure. The *Journal* of the London Chamber of Commerce, which I may remark is a very useful and interesting publication, gives the imports and exports of India for the year 1885-86 as £154,850,000, and for the year 1888-89 as £163,500,000—an increase of £8,650,000—not large, perhaps, but still an increase; and if we turn to the shipping tons engaged in the same trade a similar increase is shown. In 1885-86 the number of these tons was 6,654,000, and in 1888-89 the number was 6,983,332. We are, therefore, driven to look for an explanation elsewhere than in the trade itself. These contradictory results show two or three things, I believe—first, that decreased cost does not stimulate the demand in the case of long-distance telegrams; second, that the systematised use of codes, and possibly also that of registered addresses, has attained greater proportions; and, third, that the average of all the items which make up the external trade of India, so far as they have been affected by telegrams, must have been larger. I fear we can hardly think that we have yet touched bottom in this matter. It is one of the subjects which the International Conference, which is shortly to meet in Paris, has before it, and with which, I imagine, it will endeavour to deal. Private messages in plain language really hardly affect our business. It may be almost difficult to believe, but it is a fact that, under ordinary circumstances, these private messages in plain language do not amount to 1½ per cent. of the business passing over our lines—a most remarkable fact. You will judge, therefore, how very deeply interested we are in the coding and packing systems in the present day. Our business is to cultivate trade messages with our mercantile friends who use our lines, and I need hardly remind you that it is their business to make a given expenditure in telegrams go as far as possible—to cut down, in short, their ordinary expenses to as low a degree as possible, and to attain the greatest gain at the smallest cost. That is what we all come to the City of London for, I imagine. As I have said, the International Telegraph Conference is going to meet very shortly in Paris, at which this Company will be represented by Mr. Andrews, assisted by Mr. Moll. The losses made by low rates are now so large, and the accumulated losses so considerable, that it is to be hoped taxpayers will not be further amerced to contribute still more towards the cost of international messages sent by merchants for purposes of profit, and by wealthy travellers and others for purposes of luxury and convenience. I do not know that there are any other matters in the singularly uneventful history of the past year to which I need advert; but I would not like to sit down without expressing on behalf of the proprietors, whether shareholders or Directors, the high sense we entertain of the very efficient way in which the work of the Company is performed by the staff, from the highest to the lowest. Much of it is necessarily of a very monotonous and trying character, but it is admirably done both at home and abroad. Mr. Andrews, our esteemed Managing Director, is second to none in business capacity, and his example animates and regulates the whole work of the Company in a very remarkable way. I have now the pleasure of proposing the resolution which I have read.

Major-General G. B. TREMENHEERE, R.E., seconded the motion.

Mr. JACKSON said he thought that the Chairman, referring to the difficulties under which they laboured in connection with increasing the revenue of the Company, had "spotted" a common objection among telegraph companies when he said that private messages brought such a small amount of income. He (the speaker) did not know how this was to be remedied, but he thought it might be affected in connection with their representative at the forthcoming International Telegraph Conference at Paris by their able general manager. In the case of the Anglo-American Telegraph Company he had been assured by one of the Directors, the Marquis of Tweeddale, that a cablegram could be sent at the nominal price of 1s. a word, and that it might really cover 20 or even 24 words. He thought that this was a point that should be brought by their manager before the Conference as an illustration of the comparative unfairness of a so-called nominal tariff; and in considering this question he thought that some modification in reference to code messages should, if possible, be adopted. In face of the fact that their revenue was decreasing to a certain extent, he thought the shareholders must not expect the present handsome dividend was going to last for ever. Their concession would terminate in fourteen years. Their reserve fund was sufficient to meet all possible contingencies, and every arrangement had been made for the depreciation of the plant, which he believed was now in the most efficient condition. He thought it would only be a prudent step to make some arrangement for returning a part of the capital, and if that were done to the extent only of £1 a share, their position would be strengthened when the concession terminated, as their capital would be so small that no one, however anxious to compete, would be able to enter into the competition with them.

The CHAIRMAN: Are there any further observations or questions? Receiving no reply he continued: Mr. Jackson has made a forcible plea, not for the first time, to the Directors to consider the subject of dealing with the reserve fund within a period not so remote as the termination of our concession, as I understand him. The matter has been considered by the Board from time to time. We are in favour, I may say personally and individually, of strong reserves for all purposes, and for a great many reasons, partly connected with the terminability of the concession, and partly for reasons which have a very wide basis of uncertainty. Of course, it might suit some of our shareholders to receive back a portion of the amount of this fund by way of return and reduction of capital; but I can conceive that there are other shareholders who might take a very different view of the question, and who might prefer to see it kept in reserve until the future is much clearer than it is at present. I must not go further than to say that the subject shall continue to have our best consideration. We are all anxious to improve the line, and to extend its earning powers as far as possible, and if we could see our way to utilise a portion of our reserve fund in one or other of those ways it might be a very legitimate thing for us—speaking individually, and without consulting with my colleagues—to take into consideration. Speaking again individually, I should

Digitized by Google

be very sorry to see any repayment of capital carried into effect at present. I think the risks of the future warrant our keeping this large amount in hand and increasing it; but it might be different in the course of time, and then we shall see whether the shareholders are really of opinion that they would wish to have the money in their pockets rather than in the coffers of the Company. He then put the resolution in the usual manner, and declared it carried unanimously. Continuing, he proposed the re-election of the retiring Directors, Mr. C. Holland and Mr. H. H. Meier.

Mr. C. W. EARLE seconded the motion, which was carried unanimously; and the auditors, Messrs. C. F. Kemp, Ford and Co. were afterwards re-appointed.

Mr. JACKSON then proposed and Mr. STEVENS seconded, a vote of thanks to the Chairman, Directors, and staff; and the resolution was carried unanimously.

The CHAIRMAN: On behalf of the Directors and staff of the Company I beg to thank you for this renewed expression of your confidence and approval.

The proceedings then terminated.

Great Northern Telegraph Company of Copenhagen.

The following is an abridged report of the proceedings at the general meeting held at Copenhagen on April 26th, 1890; F. Zahle, Esq., in the chair.

The CHAIRMAN of the Company, C. F. Tietgen, Esq., in accounting for the working during the year 1889, first referred to—

The State of the Company's Cables, which, unfortunately, had left much to be desired during that period, particularly in Europe, where the cases of interruptions had numbered 19. Of this number 15 had fallen upon the three cables in the southerly section of the North Sea, the most southerly cable being that which connects France with Denmark, whilst the two others connect England with Denmark and Sweden. Nearly all these breakages had been caused by the trawl-fishing apparatus, which is still allowed to damage the cables with impunity, as the international legislation for the protection of submarine cables had not yet been extended to a control of fishing appliances. This regrettable fact had already been mentioned at the Conference held in 1883. The effects of the circumstances referred to, in addition to the constantly increasing traffic, would render it necessary for the Company to lay two new cables in the North Sea, one between France and Denmark, in order to duplicate the Calais-Faroe Cable, the only one of the Company's cables which had not yet been duplicated; and the other between England and Sweden, in order to ensure the transmission of the traffic between England and the north of Europe in the most efficient manner. Preliminary negotiations with regard to this subject had already been progressing, and the Company would do its best to accelerate the realization of its projects, more particularly as, during the early part of the year 1890, frequent interruptions had also occurred. In the far East the interruptions of the cables had been less frequent, the number having amounted to seven, none of which had interfered sensibly with the regular transmission of the traffic. In Europe, the Company's cable steamer, the "H. C. Örsted," had been in activity for 165 days during the year, and in the far East the "Store Nordiske" had been altogether on active service for 171 days.

The Working of the Lines had throughout been very satisfactory. Thanks to the efforts of the Russian Telegraph Administration, and to the introduction into Siberia of the Wheatstone system, the traffic between Europe and the far East, transmitted by the Wladiwostock route, had been carried with a regularity, speed and correctness which had left little to be desired.

The Traffic Revenue had reached about the same amount as the Company earned in the good years of 1884 and 1885, before the tariff reductions introduced at the Conference of Berlin came into force.

The Company's Position in China had not changed since last year's meeting. At the invitation of the Russian and Chinese authorities, the Company had, during two months last autumn, discussed the modifications desired to be introduced into the projected convention, which was signed at Chefoo in 1887; but notwithstanding the fact that the Company had acquiesced in all the demands of the said authorities, new obstacles to the final conclusion of the affair had arisen. They did not yet know the nature of those obstacles, for which reason they would prefer not to formulate any opinion as to the chances of arriving at a satisfactory solution.

The Company's Property.—The Company had acquired, in Copenhagen, a building site, situate at No. 26, Kongens Nytorv, and adjoining their present offices, for the purpose of erecting a building where the administration, as well as the mechanical workshops of the Company, could be located in a more practical manner than at the present, and notably less subject to the danger of fire. This measure had become a necessity on account of the development of the administration and the large increase of the archives during the progress made by the Company in the course of the last 20 years they had been in existence. The building operations had already commenced, and it would thus be explained that a somewhat larger amount than usual had been carried forward, in order to meet the current expenses under this head.

The Reserve Fund.—A rather larger amount than usual had been withdrawn from this fund, in order to defray the expense of 100 nautical miles of spare cable, to be employed in strengthening the cables in Europe. The laying of the two new projected cables already referred to would absorb, in the current year, another important amount from the reserve fund; probably, including everything, not far from £200,000. It would, therefore, have been imprudent to add less to the fund than the same amount as in previous years, the more so as they were on the eve of

An International Telegraph Conference, the decisions of which might possibly affect the revenue of the Company, as had happened before at the Telegraph Conference held at Berlin in 1885. This time the Conference would be held in Paris and would be opened on the 15th May next. All the administrations of the different States, as well as the representatives of the private telegraph companies, had been invited to take part therein. On the occasion the Company would, as usual, be represented by the managing director.

The report and balance-sheet (which appeared in our last issue) were then unanimously adopted.

The retiring Directors, C. F. Tietgen, Esq., and Capt. E. Suenson, D.R.N., were re-elected; and A. Berner, Esq., and S. Bille, Esq., were re-elected as auditors.

Five shillings per £10 share, representing the final dividend for 1889, are now payable at the Company's bankers, Messrs. C. I. Hambro and Son, No. 70, Old Broad-street, London, E.C., against Coupon No. 18.

Telephone Company of Ireland (Limited).

The eleventh ordinary general meeting of the proprietors of this Company was held at their offices, Commercial Buildings, on April 26th; Alderman Dillon, Chairman of the Company, presiding.

The SECRETARY having read the Directors' report,

The CHAIRMAN moved that the report be adopted. He said that was the first occasion on which he had to meet the shareholders in that position, although he had been with them in another position, since the inauguration of the Company. It was a source of deep regret to him that he should occupy that position in succession to two very warm friends of his—one of them one of his greatest friends, the late Mr. Gray, the first Chairman of the Company, with whom, as solicitor, he had the honour to be associated in introducing the telephone system in Ireland. They regretted also the death of Alderman Winstanley, who addressed them as Chairman at the last meeting of the Company. The Company were now to be congratulated on their progress. Since they last met an exchange had been opened in Cork, and the results there had been extremely satisfactory. From having at the commencement of the year 1889 24 subscribers to the Cork Exchange, they had on the last day of the year 295 subscribers. Their position in Cork had been somewhat peculiar. The Government or Post Office department had the control of the telephone service in Cork up to this year. That Company entered into competition with them during the year, with the result, he was glad to say, that the Government were practically beaten out of the field; and the Company had now the control of the telephone service in Cork, with subscribers to the number of nearly three hundred, although the Government, in the year that they had it, reached only a maximum of 30 subscribers. Belfast was out of their control. It was now worked by the Company with which they were associated, the National Telephone Company; but they had made arrangements with that Company for the construction of a trunk line between Dublin and Belfast, and they hoped the work would very speedily be in hand. Their development of the system in Cork had led to the result that their earnings could not be taken as representing what their future earnings would be, because they had not yet reached the advantages which would accrue to them from their expenditure in Cork. But their earnings generally had increased considerably during the past year, and now they had to divide a net earning of £8,900, as against £7,870 in the previous year. Their expenditure, both in Cork and in another direction, had been considerable. In Dublin they had replaced within the year, at a very large expense, nearly all the old iron wires, which, at the time they were laid, were considered the proper kind, by new copper wires, the life of which was very much longer indeed than that of the old iron wires. To meet this increased expenditure, but principally for the development of the trunk line to Belfast, they issued to their shareholders additional preference capital. They tried the experiment of issuing it at 5 per cent. to their Preference shareholders. He was afraid that they rather spoiled them by issuing the shares previously at 6 per cent. The result was that their shareholders did not appreciate, as they thought they ought to have done, the investment at 5 per cent., and did not take sufficient of the shares. They were, therefore, obliged to issue them now in the shape of Debentures. On this subject a special resolution would be proposed. The report also dealt with a formal matter, namely, their relations with the National Telephone Company, in consequence of which some alterations in their Articles of Association had become necessary. He had to apologise for the non-attendance of some of the Directors, with whom that happened to be a specially busy time, and who were, therefore, abliged to be absent.

Mr. ARTHUR DUDGEON seconded the motion, which was unanimously agreed to.

The CHAIRMAN moved the following resolution:—

RESOLVED:—"*That the Directors be, and they are hereby, authorised to borrow any sum or sums of money, on such security and terms, as to interest or otherwise, as they may deem fit, and may secure the same by mortgage or by other debentures, or by bonds, or by any mortgage or charge of or upon the whole or any part of any property, funds, assets, or effects of the Company, including uncalled capital, but so that not more than £35,000 be owing at any time, and that not more than £10,000 be issued without the previous consent of a general meeting.*"

Mr. ARTHUR DUDGEON seconded the above, which was unanimously carried.

The CHAIRMAN moved that the retiring Directors, Alderman V. B. Dillon and Mr. Hermann G. Erichson, be re-elected, which was seconded by Mr. ARTHUR DUDGEON, and agreed to.

Mr. WM. ANDERSON moved that Mr. John M'Kean be appointed auditor for the year ending 31st December, 1890, and that the joint remu-

Digitized by Google

neration of the auditors appointed by that Company and the United Telephone Company in liquidation be fixed at 50 guineas per annum.

Mr. EVANS seconded the motion, which was passed unanimously.

The CHAIRMAN said it was thought advisable a year ago that the great telephone companies in England should be amalgamated under one control. It was also proposed to do that by the United Telephone Company, which was the parent company, absorbing the other companies. Difficulties, however, having arisen with the Post Office it was decided to accomplish the end in view by the United Telephone Company being dissolved and formally liquidated, and its business being absorbed by the National Telephone Company, which also took over the Lancashire and Cheshire Telephone Company. The result was that the greater part of the services in England and the service in Ireland for the province of Ulster were effected by the National Telephone Company. Under the circumstances it became necessary, in order to give legal effect to the agreement which the Telephone Company of Ireland originally made with the United Telephone Company, and to transfer its obligations and concessions to the National Telephone Company, to pass a resolution making certain slight alterations in the Articles of Association of the Telephone Company of Ireland.

The CHAIRMAN read and moved these resolutions, which were of a formal character; and they were seconded by Mr. WILLIAM DUDGEON, and unanimously adopted.

Mr. WILLIAM DUDGEON moved and Mr. WILLIAM ANDERSON seconded a vote of thanks to the Chairman, which, having been passed, the proceedings terminated.

The Oriental Telephone Company (Limited).

The tenth ordinary annual general meeting of this Company was held on Tuesday, the 29th April, at the City Terminus Hotel, Cannon-street; Mr. W. Addison presiding.

The SECRETARY (Mr. Alex. B. Chalmers) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, before moving the adoption of the report and balance-sheet I have very little to add to the information therein. I think you will all allow our figures and our statements are as plain as could be wished, and, therefore, render unnecessary any long speech from me. I am glad to tell you that your Company is making steady progress, and that it is gradually strengthening its financial position. In 1884 the reserve fund, which had for the previous two years stood at £7,000, was, in order to meet the exigencies of the financial position at that time, transferred to the credit of profit and loss, and, since then, until last year, no reserve fund has existed. Your Directors, however, felt that as soon as they were in a position to do so, a new reserve fund should be formed in order that in case of need there might be a fund to fall back upon other than the uncalled capital of the Company; and in pursuance of that purpose, we placed £2,500 to reserve last year, and this year we add another £2,000. This, I am sure all will acknowledge, must add to the financial strength of your Company. Our reserve now stands at £4,500, as against £7,000 at the beginning of 1884. I will just add that the present fund is easily realisable, and indeed could be immediately used on an emergency. You will see that we have written off £500 for depreciation of stores at branches, principally at Mauritius; and we do this in order that that particular asset in our balance sheet should be fully of the value we assign to it. We carry forward this year about £550 more than we did last year; but we may, if business in the East improves, and the demand for telephonic communication increases, require a larger amount in hand than hitherto, in order that the business should not suffer for want of funds. The Directors have arranged that the balance to the credit of their current account at the bank should not exceed a certain amount, and all sums not invested beyond that should be placed on deposit, so that the Company may have the benefit of the interest. The change that has been made at Mauritius by the appointment of a Manager thoroughly acquainted with French, is likely, I think, to result in distinct advantage to us, and we hope now that that which has hitherto been a profitless exchange may help to augment our revenue. In China the business is steadily improving, and I confidently look forward to the China and Japan Company participating to a still greater extent in the general prosperity and progress which is showing itself in that hitherto very conservative country. You will see that we have not been unmindful of our promise to endeavour to come to an arrangement with the holders of the vendors' shares, but up to the present we have not succeeded. We called a meeting of those shareholders, but nothing definite was done. Your Directors think it would be most beneficial to the Company generally if both classes of shares were assimilated, and that there was only one interest instead of two conflicting ones; and we are perfectly prepared to carefully consider any suggestion for arrangement which may come from the vendors' shareholders. I have nothing further to add, and therefore beg formally to move the adoption of the report and balance-sheet. When this is seconded, I shall be glad to answer any questions which shareholders may wish to ask. I beg to move:

"*That the Directors' report, together with the balance-sheet to December 31, 1889, be approved and adopted, and that a dividend at the rate of 3 per cent., free of income-tax, for the year ended December 31, 1889, be declared on the paid-up capital of the Company other than the vendors' shares.*"

Mr. THOMAS LLOYD seconded the resolution, which was agreed to unanimously without discussion.

On the motion of Mr. B. ST. JOHN ACKERS, seconded by Mr. LLOYD, Mr. Addison was unanimously re-elected to his seat at the Board, as also was Mr. G. B. Frost, on the motion of Mr. HENRY GREWING, seconded by Mr. LLOYD.

Mr. PELL then proposed, and Mr. GIBBS seconded, the re-appointment of the auditors, Messrs. Deloitte, Devers, Griffiths, and Co., which was agreed to; and, the Chairman having been thanked for presiding, the proceedings terminated.

China and Japan Telephone Company (Limited).

The seventh ordinary general meeting of the shareholders of this Company was held at the offices, Austinfriars, yesterday (Thursday).

Mr. T. Lloyd was voted to the chair, on the motion of Mr. H. GREWING, in the absence of the Chairman of the Company, Mr. H. G. Erichsen, who telegraphed stating that he was unable to be present.

The SECRETARY (Mr. A. B. Chalmers) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: I do not think it is necessary to make any lengthy statement. I have much pleasure in saying that our business is fairly progressing. We are not making any very rapid advance; but the progress seems very satisfactory. You see we are able to carry forward a large balance, and are able to write off more for depreciation, and the Hong Kong exchange is now nearly self-supporting. I beg to move:—

"*That the Directors' report and the audited accounts for the year ended December 31, 1889, be, and the same are hereby, received and adopted.*"

Mr. GREWING seconded the motion.

Mr. A. LITTLE said that in 1882 he sold out the plant that he had purchased at Shanghai, and the goodwill, such as it was, for 937 fully paid-up shares = £937. The transaction was settled by telegraph, and he did not know that other vendors were receiving £17,000. That sum, which, he believed, was largely in excess of the value of the plant, must, of course, have been for goodwill, and he doubted very much whether the goodwill was worth anything like the sum paid for it. They had now been eight years without receiving any dividend, and it occurred to him whether it would not be a good thing not to keep the capital at an amount which it appeared to him they were never likely to receive any respectable dividend upon, and to write it down to the actual value of the plant at Shanghai and Hong Kong. It seemed to him that as long as they had a capital of £20,000, of which £14,761 was issued and £4,500 of debentures on which they paid 7 per cent., the prospect of the shareholders getting a dividend was very small. The Directors themselves absorbed very nearly half the surplus of 1888. He thought his suggestion worthy of consideration, and believed that if it could be adopted they would be on a better footing. So far as he was concerned, he would prefer to hold £400 of dividend-paying shares than £930 of nominal capital with no dividend. They would stand in a better position in China if they were known as a dividend-paying Company.

The CHAIRMAN: With respect to Mr. Little's suggestion, I can only say that the Directors will be very pleased to take it into consideration. Of course, it is not a matter that could be settled off-hand. In fact, no Director would be justified in giving an opinion without consulting with the Board. But, apart from the Board, there is one shareholder whose holding is larger than that of any one else, and that one shareholder could practically decide the matter. The suggestion will be put before the shareholder by a gentleman who is present, and who has heard what Mr. Little has said. All I can say, speaking for the Board, is, that we will take it into consideration, and we shall have it brought before the gentleman I have referred to, so that it will receive full consideration. He then put the resolution in the usual manner, and it was carried unanimously. Continuing, he proposed the re-election of Mr. Grëwing.

Mr. G. B. FROST seconded the motion, and stated that, as the representative of the Oriental Telephone Company, he would take care that Mr. Little's suggestion was placed before the Board of that Company and duly considered.

The motion was carried unanimously.

Mr. FROST proposed, "That 200 guineas be voted to the Directors for their services last year." He knew perfectly well, he said, that the Directors were doing their best and working hard to make the undertaking a paying concern, and he hoped before long that they would not only see the interest upon the Debentures paid, as had hitherto been done, but that they would also have a substantial dividend for the shareholders.

Mr. M'LEOD seconded the motion, which was carried *nem. con.*

The CHAIRMAN: I may remark, in reply to what Mr. Frost has said, that the prospects in Hong Kong are very good. As I said just now, the exchange there is nearly self-supporting. I do not wish to say more, but I think the outlook there is improving, and I hope by-and-by it will do much more than pay its way. Our advices are encouraging, certainly.

On the motion of Mr. LLOYD, seconded by Mr. FROST, Messrs. Price, Waterhouse, and Co. were re-elected auditors; and the proceedings terminated.

The following is the report of the Directors referred to by the Chairman:—

The revenue account for the year 1889, after charging debenture interest and writing off a sum of £100. 15s. 10d. in respect of depreciation of plant, &c., shows a balance of £741 to credit, which has been transferred to profit and loss account. Including the sum of £32. 16s. 4d. brought forward from last year, this account shows an amount of £773. 16s. 4d. to credit, which the Directors propose to carry forward after writing off £200 in final extinction of preliminary expenses account. At both Shanghai and Hong Kong the increase of revenue during the year has been fairly satisfactory, and the exchange at the latter place is now nearly self-supporting. As foreshadowed in a previous report, the competition in sales of material has increased, resulting in a diminution of profit from this source. In order to provide additional working capital, the Directors have issued during the present year a further £500 of debentures, bearing interest at 7 per cent. These were taken up by the Oriental Telephone

Digitized by Google

Company (Limited). The Director who retires at the present meeting is Mr. Henry Grëwing, who offers himself for re-election. Messrs. Price, Waterhouse, and Co., the auditors, also retire, and offer themselves for re-election.

The Brighton and Hove Electric Light Company.

The annual general meeting of this Company was held at the Company's offices, 47, Gloucester-road, Brighton, on the 25th ult. In the absence of Mr. Robert Hammond, the Chairman of the Company, Mr. Latham occupied the chair.

The CHAIRMAN much regretted that the Company was unable to declare a dividend, but said it would be found that the accounts were far from being unsatisfactory; and the Company might congratulate themselves upon the steady increase of their business, which, but for reasons stated in the report, would have yielded a dividend as great or even greater than that declared in past years. The reasons why no dividend was declared were (1) The reduction in the price, which was decided upon in order to give the customers the advantage of the best possible terms. (2) The running of the machinery during the day, which was arranged for the convenience of those customers who desired to use the light during the dark and foggy days, or in places where artificial lighting by day was a necessity. Unfortunately, this could not be continued, in consequence of the Board of Trade having decided that it would not be advisable to run the risk of workmen touching the wires while engaged on the roofs of houses. (3) The great advance in the price of coal, which is well known. It was to be regretted that the Company had been unable to distribute as dividend the 3½ per cent. profit made during the year, in consequence of a law suit, Garman v. the Company, having gone against them, a workman having met with an accident on the roof of one of the breweries of the town, and it was supposed that he received a shock from one of the wires which passed over the brewery. The jury delivered a verdict against the Company, and assessed damages to the amount of £800. The Company, however, is appealing against these damages, and awaits the result. Referring to the action of the Corporation the Chairman said the Directors felt that the Corporation had treated the Company most unfairly, but their experience assured them that it would be impossible to supply electricity at the present time for less than 10d. per unit unless the supply was much larger than can be expected at present, leaving out the fact that the Company was working the most economical system known. This was proved beyond all doubt by the experience of Chelmsford, where one of the Brighton Corporation's electrical advisers, Mr. Crompton, definitely said that he cannot supply at less than 1s. 4d. per unit, and this on the low-tension system adopted by the Brighton Corporation. The Company had again applied to the Board of Trade for a Provisional Order, and trusted that notwithstanding the fact that the Brighton Corporation had hitherto refused to consider any advances towards compromise on their part, some arrangement would ultimately be made. It should be borne in mind that the Company could still continue their supply by means of overhead mains, under the regulations of the Board of Trade, whatever happened; and that although they might possibly lose part of their business to the Corporation they could easily fill up their vacancies with consumers outside the Corporation's area of supply. The shareholders might be congratulated upon the election of Mr. F. W. Bentley and Mr. Arthur Kimber as Directors, the latter representing the Company's consumers and the ratepayers of the town, he being connected with several of the largest hotels in Brighton, who obtained their supply from the Company. The Chairman concluded by proposing that the report and accounts for the year ended December 31, 1889, be received and adopted.

The motion was seconded by Mr. CASH, and carried.

The retiring Directors, Mr. Robert Hammond and Mr. P. A. Latham, were re-elected.

After a cordial vote of thanks to the Chairman and Directors, the proceedings terminated.

Brazilian Submarine Telegraph Company (Limited).

Report of the Directors and the accounts for the half-year ended December 31, 1889, to be submitted to the thirty-third ordinary general meeting, to be held at the offices, Winchester House, Old Broad-street, London, E.C., on Wednesday, May 7, 1890.

The Directors submit the annexed accounts and balance-sheet for the half-year ended December 31, 1889.

The revenue for this period amounted to £121,119. 5s. 11d., and the working expenses to £15,201. 14s. 2d. After providing £12,880 for debenture interest and sinking funds, and £1,671. 14s 10d. for income-tax, there remains a balance of £91.365. 16s. 11d.; to this is added £2,609. 3s. 9d. brought forward from June 30th last, making a total of £93,975. 0s. 8d. First and second interim dividends amounting to £39,000 have been paid, and £45.000 transferred to the reserve fund, leaving the sum of £9,975. 0s. 8d. to be carried to the next account.

In accordance with the provisions for repayment of the first issue of Debentures, dated July 31, 1884, 153 bonds representing £15,300 were drawn on April 25th for payment at par on July 31st next. This, with the previous drawings, will make a total repayment of £80,800, leaving £69,200 of the first issue of Debentures outstanding.

The working expenses of the stations are £1,630 in excess of those for the previous half-year; the increased expenditure is principally due to the extension of the Company's staff quarters at St. Vincent, the furnishing thereof and the augmented staff rendered necessary by the South African traffic exchanged at St. Vincent with the cables laid to the Cape of Good Hope.

The various sections of the Company's line are in good working order.

West India and Panama Telegraph Company (Limited).

Report of the Directors and the accounts for the half-year ended December 31, 1889, to be submitted to the twenty-sixth ordinary general meeting, to be held in Room 174, Winchester House, Old Broad-street, London, E.C., on Wednesday, May 7, 1890.

The Directors submit the accounts for the six months ended December 31, 1889. The amount to credit of revenue is £42,768. 0s. 1d. (against £43,061. 16s. 9d. for the corresponding half-year of 1888), and the expenses have been £27,071. 7s. 0d. (against £21,425. 1s. 2d. for the same period in 1888), leaving a balance of £15,696. 13s. 1d., which, with the balance of £1,609. 2s. 1d., brought from last account, makes a total of £17,305. 15s. 2d., with which it is proposed to deal as follows:—

First Preference Shares—			
Dividend, 6 months to 31st December, 1889, 6s. per share	£10,368	18	0
Second Preference Shares—			
On account of arrears of dividend to 31st December, 1889, 27s. 6d. per share	6,419	17	6
Balance to current half-year's account	516	19	8
	£17,305	15	2

The traffic receipts for the six months show a decrease of £594. 12s. 7d., as compared with the corresponding period of 1888.

The large increase of £5.718. 15s. 1d. in the cost of repairing cables is accounted for by the number of interruptions having been in excess of the average, and by the expenditure of greater lengths of new cable to renew and strengthen the system in those parts where weakness or decay were proved to exist.

In a previous report the shareholders were informed that a new line of cables connecting Santiago-de-Cuba (our terminal station) with Hayti, San Domingo, Curaçoa, and Venezuela had been laid and opened for traffic by a French company, and at the three last half-yearly meetings the Chairman has referred to the possible extension of the French company's operations within this Company's system. The Directors have now to report that the French Government, in furtherance of its policy to encourage independent telegraphic enterprise by its own subjects, has entered into a convention with this new company for connecting Martinique and Guadeloupe, with a view to an eventual extension to the United States and Europe by a French line of cables; and that in pursuance of this convention, a cable (about 100 miles in length) was laid between Martinique and Guadeloupe and opened for traffic in February last, thus competing with this Company's cables between those islands. At the instance of the French Colonial Minister the annual subsidy of £2,000 hitherto paid by Martinique to this Company is held to be withdrawn by the Council General of that island, and a like subsidy has been granted to the competing company, notwithstanding that such subsidy was previously renewed to this Company up to December 31, 1890. To this manifestly unjust proceeding the Directors will offer such objections as they may be advised are open to them. Martinique and Guadeloupe are, however, still dependent on this Company's duplicated cables, comprising some 4,000 miles, for their telegraphic communications with the rest of the world, and for their daily bulletins of news and market prices, which cost this Company a large sum to collect and transmit, although the subsidy is transferred to an undertaking performing none of these obligations, and connecting these two colonies by an isolated length of only 100 miles of single cable.

In accordance with the Articles of Association, Sir James Anderson, and William Andrews, Esq., retire at this meeting, and offer themselves for re-election.

John George Griffiths, Esq., the auditor, also retires, and offers himself for re-election.

Western and Brazilian Telegraph Company (Limited).

Report of the Directors for the half-year ended December 31, 1889, to be presented at the nineteenth ordinary general meeting of the Company, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Friday, May 9th, at 12 noon.

The total earnings amount to £86,403. 0s. 7d., as against £112,250. 6s. 11d. showing a decrease of £25,847. 6s. 4d. compared with the half-year to December 31st, 1888. It will be observed that this decrease is much less than could have been expected when the shareholders met in November last; this is mainly owing to the greatly increased take during the last two months of the year, viz., November and December.

The working expenses amount to £40,391. 11s. 9d., as against £31,220. 4s. 2d., an increase of £9,171. 7s. 7d.

Including the amount brought forward from June 30, 1889 (£4,072 9s. 8d.) and the dividend received upon the shares held in the "Platino" Company, the balance to the credit of the revenue account is £57,462. 18s. 6d., from which has been deducted £13,500 for debenture interest, £7,500 for the renewal fund, and £5,600 for the debenture redemption fund. This leaves £30,862. 18s. 6d. The Directors now recommend the payment of a dividend of 6s. per share, free of income-tax, on the ordinary shares for the half-year, making, with the dividend paid in November, £4 per cent. for the year, leaving a balance of £3,248. 16s. 6d. to be carried forward.

Under Abstracts A and C, "expenses at stations and in London," the outlay is practically the same as for the corresponding period, which is a satisfactory feature considering the additional work done. In fact, out of the increased expenditure of £9,171. 7s. 7d., £7,281. 9s. 7d. is attributable

Digitized by Google

to the necessity of chartering a cable steamer to fill the place of the "Norseman," called home for repairs; this was of course imperatively necessary for the protection of the revenues, and has already been approved by the shareholders. Of the remaining increase £928. 14s. 11d. is for additional cable used in repairs; £78. 15s. for auditors' fees, and £809. 11s. 1d. for increased amounts set aside for depreciation of Company's ships. It will be remembered that the strikes at Leith delayed the repairs to the Company's steamship "Norseman," which increased the amount payable under charter. The "Norseman" returned to her station last November and the "Buccaneer" was immediately discharged.

In the case of shares which have been divided into Preferred and Deferred, 1s. 6d. per share of the dividend now recommended will be payable to the Preferred shareholders, and 4s. 6d. per share to the Deferred shareholders.

The first annual drawing of the "A" and "B" Debentures took place at the Company's offices on January 24th last, in the presence of Mr. W. W. Venn, jun., notary, when Debentures amounting to £11,200 were drawn, and have since been paid off at par.

The shareholders are aware that since the last meeting great changes have taken place in the Government of Brazil. With a view to further the shareholders' interests, the full report of the meeting of the shareholders in November last, containing the Chairman's speech and observations of the proprietors, together with a synopsis of the Company's case, were submitted to Her Majesty's Secretary of State for Foreign Affairs, with request that the influence of the British Minister in Rio de Janeiro might be brought to bear thereon. These documents appear to have convinced the Government here that the Company's case was entitled to favourable consideration; and the Foreign Office accordingly instructed Her Majesty's Minister in Rio de Janeiro to use his friendly influence on the Company's behalf, and the thanks of the Company are due to Lord Salisbury for the support thus afforded to British enterprise. The matter is still before the authorities in Brazil, and everything has been done that can be done to bring about a favourable reply.

The dividend warrants will be posted on May 15, 1890.

The International Telegraph Conference will meet at Paris in May next. The Company will be represented, as heretofore, by the managing director.

The retiring Directors are Mr. C. W. Earle and Mr. Henry Weaver, who offer themselves for re-election.

The auditors, Mr. John Weise and Mr. John G. Griffiths, retire, and are eligible for re-election.

The Anglo-Portuguese Telephone Company (Limited).

The following annual report of the Directors of this Company will be presented at the adjourned third ordinary general meeting of the Company, to be held at the offices of the Company, 53, New Broad-street, E.C., on Thursday, the 8th inst., at three o'clock:—

The profit on the year's working amounts to £5,361. 16s. 8d. After deducting £600 paid for Debenture interest, and adding £5,827. 19s. 7d. brought forward from 1888, there remains a balance of £10,589. 16s. 3d. to the credit of profit and loss account. Out of this an interim dividend of 4 per cent. has been paid, and it is now proposed to write off the £1,500 discount on Debentures issued, and to place £6,000 to a reserve fund, leaving a balance of £1,089. 16s. 3d. to be carried forward to this year's accounts. The expenditure on capital account for the year amounted to £9,731. 13s. 10d.

The number of paying subscribers at 31st December last was—

In Lisbon,	985, of a gross annual value of	£7,180
„ Oporto,	870, „ „ „	4,708
		£11,888

showing a total increase in subscribers of 222, and in value of £1,320 over the preceding year.

In order to provide for further extensions, £40,000 Eight per Cent. Second Mortgage Debentures have been created, of which £10,000 were recently offered to the shareholders of the Company in Portugal for subscription. The Directors regret to announce the retirement of the Conde De Gouvea from the Lisbon Board, and of the Company's legal adviser in Portugal, Dr. Marcal Pacheco. Mr. Arthur Henry Baker, of the London Board, and Senhor Jorge O'Neill O'Neill, of the Lisbon Board, are the retiring Directors at the forthcoming general meeting, and being eligible offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., being eligible, offer themselves for re-election.

House-to-House Electric Light Supply Company (Limited).

The following is the report of the Directors to be presented at the second ordinary general meeting to be held at the Central Electric Lighting Station, Richmond-road, West Brompton, on Monday, May 5, 1890:—

In submitting to the shareholders the report of the operations of the Company to December 31, 1889, the Directors have pleasure in reporting the satisfactory progress of the business of the Company.

The total number of shares issued is 8,322 ordinary shares of £5 each, and 100 founders' shares of £5; and in order to meet the further requirements of the Company, the Directors have issued £30,000 Debentures, convertible into ordinary shares, which will provide plant at the Kensington station capable of supplying houses wired for over 25,000 lamps, consuming 33 watts.

Parliamentary powers, under the Electric Lighting Acts, 1882-1888, giving the Company 42 years' tenure in a wealthy residential district at Kensington, have been granted to the Company. The district contains:—

District.	South.	North.	Total.
Private houses	5,734	7,120	12,854
Shops	642	1,608	2,250
Churches and chapels	15	24	39
Hotels and public houses	39	66	105
Public buildings, including Board schools	4	10	14
Rateable value	£573,097	£368,274	£941,371

Since these powers have been granted and the supply mains laid, there has been a steady increase in the Company's business. The Company's mains now extend throughout seven miles of the principal streets of the area allotted to the Company by Parliament, reaching the extreme end of the eastern and southern boundaries at Sumner-place and the Fulham-road respectively.

Since October 1, 1889 (the date the Company obtained power to lay supply mains in the public streets), orders for the supply of electricity have been received at the rate of about 400 lights per week, making at present a total of over 12,000 lights. The number of lights at present connected to the Company's mains is about 7,000, and the revenue from these lights already covers the whole of the working expenses, and the depreciation and establishment charges; so that a considerable profit will accrue when the extension of the lighting is brought up to the full power of the plant, as no further capital expenditure will be required, and the cost of producing the current will be relatively much reduced.

The net revenue from the station (including the additional unit of plant for which capital has been provided) when in full work, is calculated at £8,000 per annum, after allowing £7,000 per annum for working expenses, depreciation, &c.

Digitized by Google

After giving a list of the present installations of the Company, the report continues:—

The Central Electric Lighting station which has been erected by the Company at Kensington is generally admitted to be the most perfectly equipped Central Electricity Supply station that has yet been erected. The machinery is divided into three units of plant, each capable of producing electricity for 3,000 33-watt incandescent lamps burning at one time. The station is designed for 12 of such sets of plant, with a capacity for supplying about 100,000 lamps, installed in about 2,000 houses, and it is the Directors' intention to issue further capital from time to time to provide for laying down the additional units, as the business of the Company extends.

The excellency of the engineering work done by the Company in planning and laying down the Kensington Station is so generally recognised, that the Directors are continually receiving enquiries from Supply Companies and Local Authorities throughout the United Kingdom, with a view to their contracting for laying down similar electric lighting stations elsewhere.

The following is a list of the Companies which have been registered by this Company, and of which this Company holds the whole of the founders' shares, entitled to half the profits after 7 per cent. has been paid on the respective capitals:—The Lancashire and Cheshire, the Yorkshire, the Northern, the Liverpool, the Birmingham, the Manchester, the Midland, the Western, the South of England, the Scottish, and the Irish House-to-House Electricity Companies (Limited). The Company holds a portion of the founders' shares in the following Companies:—The Devon and Cornwall Electricity Supply Company (Limited); the Portsmouth and South Hants Electricity Supply Company (Limited); the Sunderland and District Electricity Supply Company (Limited).

[Lists follow of the provincial towns and London parishes for which these Companies are applying for Provisional Orders.]

As favourable business arises in connection with these Provisional Orders, further issues of capital will be made.

The increasing favour with which householders are regarding the use of the electric light affords a field for the operations of the Company which is practically unlimited, and the moderate capital upon which the Company has to pay a dividend bears marked contrast to the capital of other companies seeking for similar business. Moreover, this Company has an immense advantage in being able to show a sample of its work in successful operation, and in having at its command the services of engineers who have been connected with House-to-House Electric Lighting from central stations from the beginning.

The retiring Directors are Mr. Henry Ramié Beeton and Mr. Robert Hammond, who, being eligible, offer themselves for re-election.

The auditors, Messrs. Theobald Bros. and Miall also retire, and offer themselves for re-election.

Submarine Cables Trust.

The following is the report of the Trustees to the nineteenth ordinary annual meeting of the certificate holders, to be held at the offices, 50, Old Broad-street, E.C., on Wednesday, the 7th inst. at one o'clock.

The revenue for the financial year to April 15, 1890, including the balance of £165. 1s. 6d., brought from the previous accounts, amounted to £23,259. 6s. 10d.

The coupon due on October 15, 1888, was paid in two instalments, viz., £2. 12s. 6d. on April 15, 1889, and the balance of 7s 6d. on May 15th last. The first payment of £2. 12s. 6d. was included in the previous year's accounts, but the balance of 7s. 6d. was a charge against the revenue for the past year. The expenses of the Trust amounted to £1,274. 0s. 5d., and the payments on account of the coupons to £21,553. 17s. 6d., together £22,827. 17s. 11d., leaving a balance of £431. 8s. 11d. to be carried forward. In addition to paying the 7s. 6d. outstanding on the October, 1888, coupons, the coupons due on April 15th and October 15th, 1889, have been met in full out of the revenue for the past year. The certificate holders have thus received interest at the rate of 6¾ per cent. in the past year, as against 5§ in the previous year. The coupons due on April 15, 1890, are in arrear, and will be paid as soon as the Trustees have sufficient money in hand for the purpose.

The Trustees regret the loss sustained in October last by the death of Sir Daniel Gooch, Bart., who was connected with the Trust since its formation. The Trustees do not recommend that the vacancy thus occasioned in their number be filled up, the remaining Trustees being quite competent to manage the Trust. An appreciable saving in the expenses will thereby be effected.

The meeting will have to elect two auditors for the current year; Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

NEW COMPANIES REGISTERED.

J. A. EGESTORFF AND COMPANY (LIMITED).—Objects: To acquire and carry on the business of colour manufacturers, in all its branches, tin manufactures, electrical engineers miners, mine owners, and mineral works, and particularly that of Messrs. Egestorff and Son, of Backbarrow, in the county of Lancaster, adopting therefor an agreement made April 17, 1890, with Johannes Augustus Egestorff, of Backbarrow House, for the sale of the said business, and the properties connected therewith, for the sum of £3,800, of which £800 is to be paid in cash, and the residue in shares of the company. Capital, £10,000, in £5 shares. With few exceptions, the regulations contained in Table A apply. First managing director, the said Johannes Augustus Egestorff, at a remuneration of £400 per annum. Registered, April 24, by Waterlow and Sons (Limited), London-wall, for Salmon, Daniell, and Major, solicitors, Ulverston.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY.—Objects: To carry on the businesss of telephone and telegraph companies in the Republic of Venezuela and elsewhere, and act as contractors for the supply of electricity for lighting and other purposes. Capital £70,000, in £1 shares. Borrowing limit £70,000. Registered, April 22nd, by Ashurst, Morris, Crisp, and Co., solicitors, 6, Old Jewry, London.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended April 25 amounted to £4,709.

BRITISH GUIANA ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—This Company has recently been floated, with a capital of $50,000 in 2,000 shares of $25 each, 1,000 only of the shares being offered for subscription under the present prospectus. The directors are: Messrs. Jacob Conrad, Chairman; Hon. B. Howell Jones, Arthur Braud, Arthur Weber, John Braud, E. T. White, M. Gonsalves. The consulting electrician is Mr. Samuel Vyle, and the secretary *(pro tem.)*, Mr. Thomas Watt. The Company has been formed to carry on in this colony public and private electric lighting and the supply of power for railroad, car, and other purposes, on the Thomson-Houston system. It is intended to commence operations for the lighting of private residences, churches, public institutions, places of business, and so on; and that the supply shall be furnished through meter or at fixed rates per lamp. The Directors congratulate the new Company on having secured the services of Mr. Vyle, who has had considerable experience in electric lighting, and whose complete scientific and practical knowledge is a guarantee to the British public for the efficient carrying out of the objects for which the new Company has been formed.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.—The Directors of this Company recommend a further dividend of 3½ per cent., making a total of 6 per cent. for the past year.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—A meeting of the shareholders of this Company was held yesterday (Thursday), but, the proceedings being private, no reporters were admitted.

SWAN UNITED ELECTRIC LIGHT COMPANY.—The Directors of this Company have decided to pay an *ad interim* dividend at the rate of 6 per cent. per annum for the six months ended March 31, 1890, to be distributed in accordance with the Articles of Association.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended April 25th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,652.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-60in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

FACTORY.
